Bounding Equilibrium Payoffs in Repeated Games with Private Monitoring*

Abstract

We provide a simple sufficient condition for the existence of a recursive upper bound on (the Pareto frontier of) the sequential equilibrium payoff set at a fixed discount factor in two-player repeated games with imperfect private monitoring. The bounding set is the sequential equilibrium payoff set with perfect monitoring and a mediator. We show that this bounding set admits a simple recursive characterization, which nonetheless necessarily involves the use of private strategies. Under our condition, this set describes precisely those payoff vectors that arise in equilibrium for some private monitoring structure, if either non-stationary monitoring or communication is allowed.

*This replaces our earlier paper, “Perfect Versus Imperfect Monitoring in Repeated Games.” For helpful comments, we thank Dilip Abreu, Gabriel Carroll, Henrique de Oliveira, Glenn Ellison, Drew Fudenberg, Michihiro Kandori, George Mailath, Hitoshi Matsushima, Stephen Morris, Ilya Segal, Tadashi Sekiguchi, Andrzej Skrzypacz, Satoru Takahashi, Juuso Toikka, Thomas Wiseman, the anonymous referees, and participants in several seminars.
1 Introduction

Like many dynamic economic models, repeated games are typically studied using recursive methods. In an incisive paper, Abreu, Pearce, and Stacchetti (1990; henceforth APS) recursively characterized the perfect public equilibrium payoff set at a fixed discount factor in repeated games with imperfect public monitoring. Their results (along with related contributions by Fudenberg, Levine, and Maskin (1994) and others) led to fresh perspectives on problems like collusion (Green and Porter, 1984; Athey and Bagwell, 2001), relational contracting (Levin, 2003), and government credibility (Phelan and Stacchetti, 2001). However, other important environments—like collusion with secret price cuts (Stigler, 1964) or relational contracting with subjective performance evaluations (Levin, 2003; MacLeod, 2003; Fuchs, 2007)—involve imperfect private monitoring, and it is well-known that the methods of APS do not easily extend to such settings (Kandori, 2002). Whether the equilibrium payoff set in repeated games with private monitoring exhibits any tractable recursive structure at all is thus a major question.

In this paper, we do not make any progress toward giving a recursive characterization of the sequential equilibrium payoff set in a repeated game with a given private monitoring structure. Instead, working in the context of two-player games, we provide a simple condition for the existence of a recursive upper bound on the Pareto frontier of this set. The key feature of our bound is that it is tight from the perspective of an observer who does not know the monitoring structure under which the game is being played: that is, our bound characterizes the set of payoffs that can arise in equilibrium for some monitoring structure. In other words, from the perspective of an observer who knows the monitoring structure, our results give an upper bound on how well the players can do; while from the perspective of an observer who does not know the monitoring structure, our results exactly characterize how well they can do. Which of these two perspectives on our results is more relevant for a particular application thus depends on the observability of the monitoring structure to an outsider, which can be expected to vary from application to application.

The set we use to upper-bound the equilibrium payoff set with private monitoring is the

---

1For conciseness, henceforth we will say that a set of payoff vectors $X$ upper-bounds set $Y$ if every payoff vector $y \in Y$ is Pareto dominated by some payoff vector $x \in X$. This is obviously not the same as $X \supseteq Y$. 

1
equilibrium payoff set with perfect monitoring and a mediator (mediated perfect monitoring). We do not take a position on the realism of allowing a mediator, and instead view the model with a mediator as a purely technical device that is useful for bounding equilibrium payoffs with private monitoring. We thus show that the equilibrium payoff set with private monitoring admits a recursive upper bound by establishing two main results:

1. Under a simple condition, the equilibrium payoff set with mediated perfect monitoring is an upper bound on the equilibrium payoff set with any private monitoring structure.

2. The equilibrium payoff set with mediated perfect monitoring has a recursive structure.

It might seem surprising that any conditions at all are needed for the first of these results, as one might think that improving the precision of the monitoring structure and adding a mediator can only expand the equilibrium set. But this is not the case: giving a player more information about her opponents’ past actions splits her information sets and thus gives her new ways to cheat, and indeed we show by example that (unmediated) imperfect private monitoring can sometimes outperform (mediated) perfect monitoring. In other words, perfect monitoring is not necessarily the optimal monitoring structure in a repeated game, even if it is advantaged by giving the players access to a mediator.

Our sufficient condition for mediated perfect monitoring to outperform any private monitoring structure is that there is a feasible payoff vector \( v \) such that no player \( i \) is tempted to deviate if she gets continuation payoff \( v_i \) when she conforms and is minmaxed when she deviates. This is a joint restriction on the stage game and the discount factor, and it is essentially always satisfied when players are at least moderately patient. (However, they need not be patient enough for the folk theorem to apply.) Under this condition, we show that the Pareto frontier of the equilibrium payoff set under mediated perfect monitoring coincides with that under the universal monitoring structure that arises when the mediator perfectly observes all actions but each player observes only her own actions. Our first main result follows because, as its name suggests, the universal monitoring structure embeds any private monitoring structure.

To understand our second main result, recall that, in repeated games with perfect monitoring without a mediator, all strategies are public, so the sequential (equivalently, subgame
perfect) equilibrium set coincides with the perfect public equilibrium set, which was recursively characterized by APS. On the other hand, with a mediator—who makes private action recommendations to the players—private strategies play a crucial role, and APS’s characterization does not apply. Nonetheless, under the sufficient condition for our first result, a recursive characterization is obtained by replacing APS’s generating operator $B$ with what we call the minmax-threat generating operator $\tilde{B}$: for any set of continuation payoffs $W$, the set $\tilde{B}(W)$ is the set of payoffs that can be attained when on-path continuation payoffs are drawn from $W$ and deviators are minmaxed. To see why deviators can always be minmaxed in the presence of a mediator—and also why private strategies cannot be ignored—suppose that the mediator recommends a target action profile $a \in A$ with probability $1 - \varepsilon$, while recommending every other action profile with probability $\varepsilon/(|A| - 1)$; and suppose further that if some player $i$ deviates from her recommendation, the mediator then recommends that her opponents minmax her in every future period. In such a construction, player $i$’s opponents never learn that a deviation has occurred, and they are therefore always willing to follow the recommendation of minmaxing player $i$.\(^2\) (This construction clearly relies on private strategies: if the mediator’s recommendations were public, players would always see when a deviation occurs, and they then might not be willing to minmax the deviator.)

We consider several extensions of our results. Perhaps most importantly, we establish two senses in which the equilibrium payoff set with mediated perfect monitoring is a tight upper bound on the equilibrium payoff set, from the perspective of an observer who does not know the monitoring structure. First, mediated perfect monitoring with a given strategy of the mediator’s itself induces a nonstationary monitoring structure, meaning that the distribution of signals can depend on everything that has happened in the past, rather than only on current actions. Thus, our upper bound is trivially tight from the perspective of an observer who finds nonstationary monitoring structures possible. Second, restricting attention to standard, stationary monitoring structures—where the signal distribution depends only on the current actions—we show that the mediator can be dispensed with if the players have access to an ex ante correlating device and cheap talk communication. Hence, our upper

\(^2\)In this construction, the mediator virtually implements the target action profile. For other applications of virtual implementation in games with a mediator, see Lehrer (1992), Mertens, Sorin, and Zamir (2015, IV.4.b), Renault and Tomala (2004), Rahman and Obara (2010), and Rahman (2012).
bound is also tight from the perspective of an observer who finds only stationary monitoring structures possible, if she also accepts the possibility of ex ante correlation and cheap talk.

This paper is not the first to develop recursive methods for repeated games with imperfect private monitoring. Kandori and Matsushima (1998) augment private monitoring repeated games with opportunities for public communication among the players and provide a recursive characterization of a subset of equilibrium payoffs that is large enough to yield a folk theorem. Tomala (2009) gives related results when the repeated game is augmented with a mediator rather than only public communication. Neither paper provides a recursive upper bound on the entire sequential equilibrium payoff set for a fixed discount factor.\(^3\) Amarante (2003) does give a recursive characterization of the equilibrium payoff set in private monitoring repeated games, but the state space in his characterization is the set of repeated game histories, which grows over time. Phelan and Skrzypacz (2012) and Kandori and Obara (2010) develop recursive methods for checking whether a given finite-state strategy profile is an equilibrium in a private monitoring repeated game.

Awaya and Krishna (2015) and Pai, Roth, and Ullman (2014) derive bounds on payoffs in private monitoring repeated games as a function of the monitoring structure. The bounds in these papers come from the observation that, if an individual’s actions can have only a small impact on the distribution of signals, then the shadow of the future can have only a small effect on her incentives. In contrast, our payoff bounds apply for all monitoring structures, including those in which individual actions have a large impact on the signal distribution.

Finally, we have emphasized that our results can be interpreted either as giving an upper bound on the equilibrium payoff set in a repeated game for a particular private monitoring structure or as characterizing the set of payoffs that can arise in equilibrium for some private monitoring structure. With the latter interpretation, our paper shares a motivation with Bergemann and Morris (2013), who characterize the set of payoffs that can arise in equilibrium in a static incomplete information game for some information structure. Yet another interpretation of our results is that they establish that information is valuable in

\(^3\)Ben-Porath and Kahneman (1996) and Compte (1998) also prove folk theorems for private monitoring repeated games with communication, but they do not emphasize recursive methods away from the \(\delta \to 1\) limit. Lehrer (1992), Mertens, Sorin, and Zamir (2015, IV.4.b), and Renault and Tomala (2004) characterize the communication equilibrium payoff set in undiscounted repeated games. These papers study how imperfect monitoring can limit the equilibrium payoff set without discounting, while our focus is on how discounting can limit the equilibrium payoff set independently of the monitoring structure.
mediated repeated games, in that—under our sufficient condition—players cannot benefit from imperfections in the monitoring technology. This interpretation connects our paper to the literature on the value of information in static incomplete information games (e.g., Gossner, 2000; Lehrer, Rosenberg, and Shmaya, 2010; Bergemann and Morris, 2013).

The rest of the paper is organized as follows. Section 2 describes our models of repeated games with private and mediated perfect monitoring, which are standard. Section 3 gives an example showing that private monitoring can sometimes outperform mediated perfect monitoring. Section 4 develops preliminary results about repeated games with mediated perfect monitoring. Section 5 presents our first main result: a sufficient condition for mediated perfect monitoring to outperform private monitoring. The proof of this result is deferred to Section 8. Section 6 presents our second main result: a recursive characterization of the equilibrium payoff set with mediated perfect monitoring. Section 7 illustrates the calculation of the upper bound with an example. Section 9 discusses the tightness of our upper bound, as well as partial versions of our results that apply when our sufficient conditions do not hold, as in the case of more than two players. Section 10 concludes.

2 Repeated Games with Private and Mediated Perfect Monitoring

A finite stage game \( G = (I, (A_i, u_i)_{i \in I}) \) is repeated in periods \( t = 1, 2, \ldots \), where \( I = \{1, \ldots, |I|\} \) is the set of players, \( A_i \) is the finite set of player \( i \)'s actions, and \( u_i : A \rightarrow \mathbb{R} \) is player \( i \)'s payoff function. Players maximize expected discounted payoffs with common discount factor \( \delta \).

2.1 Private Monitoring

In each period \( t \), the game proceeds as follows: Each player \( i \) takes an action \( a_{i,t} \in A_i \). A signal \( z_t = (z_{i,t})_{i \in I} \in \prod_{i \in I} Z_i = Z \) is drawn from distribution \( p(z_t | a_t) \), where \( Z_i \) is the finite set of player \( i \)'s signals and \( p(\cdot | a) \) is the monitoring structure. Player \( i \) observes \( z_{i,t} \).

A period \( t \) history of player \( i \)'s is an element of \( H^t_i = (A_i \times Z_i)^{t-1} \), with typical element \( h^t_i = (a_{i,\tau}, z_{i,\tau})_{\tau=1}^{t-1} \), where \( H^1_i \) consists of the null history \( \emptyset \). A (behavior) strategy of player
An assessment \((\sigma, \beta)\) constitutes a sequential equilibrium if the following two conditions are satisfied:

1. [Sequential rationality] For each player \(i\) and history \(h^t_i\), \(\sigma_i\) maximizes player \(i\)'s expected continuation payoff at history \(h^t_i\) under belief \(\beta_i(h^t_i)\).

2. [Consistency] There exists a sequence of completely mixed strategy profiles \((\sigma^n)\) such that the following two conditions hold:

   (a) \(\sigma^n\) converges to \(\sigma\) (pointwise in \(t\)): For all \(\varepsilon > 0\) and \(t\), there exists \(N\) such that, for all \(n > N\), \(|\sigma^n_i(h^t_i) - \sigma_i(h^t_i)| < \varepsilon\) for all \(i \in I, h^t_i \in H^t_i\).

   (b) Conditional probabilities converge to \(\beta\) (pointwise in \(t\)): For all \(\varepsilon > 0\) and \(t\), there exists \(N\) such that, for all \(n > N\),

   \[
   \left| \frac{\Pr^\sigma(h^t_i, h^t_{-i}) - \beta_i(h^t_i | h^t_i)}{\sum_{h^t_{-i}} \Pr^\sigma(h^t_i, h^t_{-i})} \right| < \varepsilon \text{ for all } i \in I, h^t_i \in H^t_i, h^t_{-i} \in H^t_{-i}.
   \]

This relatively permissive definition of consistency (requiring that strategies and beliefs converge only pointwise in \(t\)) gives a weakly larger set of equilibrium payoffs to be bounded but also allows more freedom in constructing the bounding equilibria. However, by replacing infinite punishments with long finite punishments, our equilibrium constructions can be modified to satisfy consistency under uniform convergence.

### 2.2 Mediated Perfect Monitoring

In each period \(t\), the game proceeds as follows: A mediator sends a private message \(m_{i,t} \in M_i\) to each player \(i\), where \(M_i\) is a finite message set for player \(i\). Each player \(i\) takes an action \(a_{i,t} \in A_i\). All players and the mediator observe the action profile \(a_t \in A\).
A period $t$ history for the mediator is an element of $H^t_m = (M \times A)^{t-1}$, with typical element $h^t_m = (m_\tau, a_\tau)_{\tau=1}^{t-1}$, where $H^1_m$ consists of the null history. A strategy for the mediator is a map $\mu : \bigcup_{t=1}^\infty H^t_m \rightarrow \Delta(M)$. A period $t$ history of player $i$’s is an element of $H^t_i = (M_i \times A)^{t-1} \times M_i$, with typical element $h^t_i = ((m_{i,\tau}, a_\tau)_{\tau=1}^{t-1}, m_{i,t})$, where $H^1_i = M_i$.

A strategy of player $i$’s is a map $\sigma_i : \bigcup_{t=1}^\infty H^t_i \rightarrow \Delta(A_i)$.

The definition of sequential equilibrium is the same as with private monitoring, except that sequential rationality is imposed (and beliefs are defined) only at histories consistent with the mediator’s strategy. The interpretation is that the mediator is not a player in the game but rather a “machine” that cannot tremble.\footnote{We also occasionally write $h^t_i$ for $(m_{i,\tau}, a_\tau)_{\tau=1}^{t-1}$, omitting the period $t$ message $m_{i,t}$.} Note that with this definition an assessment (including the mediator’s strategy) $(\mu, \sigma, \beta)$ is a sequential equilibrium with mediated perfect monitoring if and only if $(\sigma, \beta)$ is a sequential equilibrium with the “nonstationary” private monitoring structure where $Z_i = M_i \times A$ and $p_i(\cdot | h^t_{m+1})$ coincides with perfect monitoring of actions with messages given by $\mu(h^t_{m+1})$ (see Section 9.1).

As in Forges (1986) and Myerson (1986), any equilibrium distribution over action paths arises in an equilibrium of the following form:

1. [Messages are action recommendations] $M = A$.

2. [Obedience/incentive compatibility] At history $h^t_i = ((m_{i,\tau}, a_\tau)_{\tau=1}^{t-1}, m_{i,t})$, player $i$ plays $a_{i,t} = m_{i,t}$.

Without loss of generality, we restrict attention to such obedient equilibria throughout.\footnote{The assumption that the mediator cannot tremble does not matter for our results.} We denote the mediator’s action recommendation by $r \in A$.

Finally, we say that a sequential equilibrium with mediated perfect monitoring is on-path strict if following the mediator’s recommendation is strictly optimal for each player $i$ at every on-path history $h^t_i$. Let $E_{\text{med}}(\delta)$ denote the set of on-path strict sequential equilibrium payoffs. For the rest of the paper, we slightly abuse terminology by omitting the qualifier “on-path” when discussing such equilibria.

\footnote{Dhillon and Mertens (1996) show that the revelation principle fails for trembling-hand perfect equilibria. Nonetheless, with our “machine” interpretation of the mediator, the revelation principle applies for sequential equilibrium by precisely the argument of Forges (1986).}
3 An Illustrative (Counter)Example

The goal of this paper is to provide sufficient conditions for the equilibrium payoff set with mediated perfect monitoring to upper-bound the equilibrium payoff set with private monitoring. We first provide an illustrative example showing why, in the absence of our sufficient conditions, private monitoring (without a mediator) can outperform mediated perfect monitoring. Readers eager to get to the results can skip this section without loss of continuity.

Consider the repetition of the following stage game, with $\delta = \frac{1}{6}$:

$$
\begin{array}{ccc}
L & M & R \\
U & 2,2 & -1,0 & -1,0 \\
D & 3,0 & 0,0 & 0,0 \\
T & 0,3 & 6,-3 & -6,-3 \\
B & 0,-3 & 0,3 & 0,3 \\
\end{array}
$$

Example 1

**Proposition 1** In Example 1, there is no sequential equilibrium where the players’ per-period payoffs sum to more than 3 with mediated perfect monitoring, while there is such a sequential equilibrium with some private monitoring structure.

**Proof.** See Appendix 10. ■

Let us sketch the proof of Proposition 1. Note that $(U, L)$ is the only action profile where payoffs sum to more than 3. Because $\delta$ is low, player 1 (row player, “she”) can be induced to play $U$ in response to $L$ only if action profile $(U, L)$ is immediately followed by $(T, M)$ with high enough probability: specifically, this probability must exceed $\frac{3}{5}$. With perfect monitoring, player 2 (column player, “he”) must then “see $(T, M)$ coming” with probability at least $\frac{3}{5}$ following $(U, L)$, and this probability is so high that player 2 will deviate from $M$ to $L$ (regardless of the specification of continuation play). This shows that payoffs cannot sum to more than 3 with perfect monitoring.

On the other hand, with private monitoring, player 2 may not know whether $(U, L)$ has just occurred, and therefore may be unsure of whether the next action profile will be $(T, M)$ or $(B, M)$, which can give him the necessary incentive to play $M$ rather than $L$. In particular,
suppose that player 1 mixes \( \frac{1}{3}U + \frac{2}{3}D \) in period 1, and the monitoring structure is such that player 2 gets signal \( m \) (“play \( M \)”) with probability 1 following \((U, L)\), and gets signals \( m \) and \( r \) (“play \( R \)”) with probability \( \frac{1}{2} \) each following \((D, L)\). Suppose further that player 1 plays \( T \) in period 2 if she played \( U \) in period 1, and plays \( B \) in period 2 if she played \( D \) in period 1. Then, when player 2 sees signal \( m \) in period 1, his posterior belief that player 1 played \( U \) in period 1 is
\[
\frac{\frac{1}{3}(1)}{\frac{1}{3}(1) + \frac{2}{3}(\frac{1}{2})} = \frac{1}{2}.
\]
Player 2 therefore expects to face \( T \) and \( B \) in period 2 with probability \( \frac{1}{2} \) each, so he is willing to play \( M \) rather than \( L \). Meanwhile, player 1 is always rewarded with \((T, M)\) in period 2 when she plays \( U \) in period 1, so she is willing to play \( U \) (as well as \( D \)) in period 1.

To summarize, the advantage of private monitoring is that pooling players’ information sets (in this case, player 2’s information sets after \((U, L)\) and \((D, L)\)) can make providing incentives easier.\(^7\) A companion paper (Sugaya and Wolitzky, 2016) develops this point in the context of some canonical models in industrial organization.

Below, we show that private monitoring cannot outperform mediated perfect monitoring when there exists a feasible payoff vector \( v \) such that no player \( i \) is tempted to deviate if she gets continuation payoff \( v_i \) when she conforms and is minmaxed when she deviates. This condition is violated in the current example because, when \( \delta = \frac{1}{6} \), no feasible continuation payoff for player 2 is high enough to induce him to respond to \( T \) with \( M \) rather than \( L \). Specifically, in the example the condition holds if and only if \( \delta \geq \frac{19}{23} \).

\section{Preliminary Results about \( E_{med}(\delta) \)}

We begin with two preliminary results about the equilibrium payoff set with mediated perfect monitoring. These results are important for both our result on when private monitoring cannot outperform mediated perfect monitoring (Theorem 1) and our characterization of

\(^7\)As far as we know, the observation that players in a repeated game can benefit from imperfections in monitoring even in the presence of a mediator is original. Examples by Kandori (1991), Sekiguchi (2002), Mailath, Matthews, and Sekiguchi (2002), and Miyahara and Sekiguchi (2013) show that players can benefit from imperfect monitoring in finitely repeated games. However, in their examples this conclusion relies on the absence of a mediator, and is thus due to the possibilities for correlation opened up by private monitoring. The broader point that giving players more information can be bad for incentives is of course familiar.
the equilibrium payoff set with mediated perfect monitoring (Theorem 2).

Let $u_i$ be player $i$'s correlated minmax payoff, given by

$$u_i = \min_{\alpha_{-i} \in \Delta(A_{-i})} \max_{a_i \in A_i} u_i(a_i, \alpha_{-i}).$$

Let $\alpha^*_{-i} \in \Delta(A_{-i})$ be a solution to this minmax problem. Let $d_i$ be player $i$’s greatest possible gain from a deviation at any recommendation profile, given by

$$d_i = \max_{r \in A, a_i \in A_i} u_i(a_i, r_{-i}) - u_i(r).$$

Let $w_i$ be the lowest continuation payoff such that player $i$ does not want to deviate at any recommendation profile when she is minmaxed forever if she deviates, given by

$$w_i = u_i + \frac{1 - \delta}{\delta} d_i.$$

Let

$$W_i = \{ w \in \mathbb{R}^{|I|} : w_i \geq w_i \}.$$

Finally, let $\mathcal{F}$ be the convex hull of the set of feasible payoffs, let

$$W^* = \bigcap_{i \in I} W_i \cap \mathcal{F},$$

and denote the interior of $W^*$ as a subspace of $\mathcal{F}$ by $\tilde{W}^*$.

Our first preliminary result is that all payoffs in $\tilde{W}^*$ are attainable in equilibrium with mediated perfect monitoring. See Figure 1. The intuition is that the mediator can virtually implement any payoff vector in $W^*$ by minmaxing deviators.

We will actually prove the slightly stronger result that all payoffs in $\tilde{W}^*$ are attainable in a strict “full-support” equilibrium with mediated perfect monitoring. Formally, we say that an equilibrium has full support if for each player $i$ and history $h_i^t = (r_{i,\tau}, a_{\tau})_{\tau=1}^{t-1}$ such that there exist recommendations $(r_{-i,\tau})_{\tau=1}^{t-1}$ with $\Pr^\mu(r_{\tau}|(r_{\tau'}, a_{\tau'})_{\tau'=1}^{\tau-1}) > 0$ for each $\tau = 1, ..., t-1$,
there exist alternative recommendations \( (\bar{r}_{-i,\tau})^{\tau-1}_{\tau=1} \) such that for each \( \tau = 1, \ldots, t-1 \) we have

\[
\Pr^\mu(\bar{r}_{i,\tau}, \bar{r}_{-i,\tau} | (\bar{r}_{i,\tau'}, \bar{r}_{-i,\tau'}, a_{\tau'})^{\tau-1}_{\tau=1}) > 0 \quad \text{and} \quad \bar{r}_{-i,\tau} = a_{-i,\tau}.
\]

That is, any history \( h_i^t \) consistent with the mediator’s strategy is also consistent with \( i \)'s opponents’ equilibrium strategies (even if player \( i \) herself has deviated, noting that we allow \( r_{i,\tau} \neq a_{i,\tau} \) in \( h_i^t \)). This is weaker than requiring that the mediator’s recommendation has full support at all histories (on- and off-path), but stronger than requiring that the recommendation has full support at all on-path histories only. Note that, if the equilibrium has full support, player \( i \) never believes that any of the other players has deviated.

**Lemma 1** For all \( v \in \hat{W}^* \), there exists a strict full-support equilibrium with mediated perfect monitoring with payoff \( v \). In particular, \( W^* \subseteq E_{\text{med}}(\delta) \).

**Proof.** For each \( v \in \hat{W}^* \), there exists \( \mu \in \Delta(A) \) such that \( u(\mu) = v \) and \( \mu(r) > 0 \) for all \( r \in A \). On the other hand, for each \( i \in I \) and \( \varepsilon \in (0, 1) \), approximate the minmax strategy \( \alpha_{-i} \) by the full-support strategy \( \alpha_{-i}^\varepsilon \equiv (1 - \varepsilon) \alpha_{-i} + \varepsilon \sum_{a_{-i} \in A_{-i}} \frac{a_{-i}}{|A_{-i}|} \). Since \( v \in \text{int}(\bigcap_{i \in I} W_i) \), there exists \( \varepsilon \in (0, 1) \) such that, for each \( i \in I \), we have

\[
v_i > \max_{a_i \in A_i} u_i(a_i, \alpha_{-i}^\varepsilon) + \frac{1 - \delta}{\delta} d_i.
\]

Consider the following recommendation schedule: The mediator follows an automaton strategy whose state is identical to a subset of players \( J \subseteq I \). Hence, the mediator has \( 2^{|I|} \)
states. In the following construction of the mediator’s strategy, \( J \) will represent the set of players who have ever deviated from the mediator’s recommendation.

If the state \( J \) is equal to \( \emptyset \) (no player has deviated), then the mediator recommends \( \mu \). If there exists \( i \) with \( J = \{i\} \) (only player \( i \) has deviated), then the mediator recommends \( r_{-i} \) to players \(-i\) according to \( \alpha_{-i}^{\varepsilon} \), and recommends some best response to \( \alpha_{-i}^{\varepsilon} \) to player \( i \). Finally, if \(|J| \geq 2\) (several players have deviated), then for each \( i \in J \), the mediator recommends the best response to \( \alpha_{-i}^{\varepsilon} \), while she recommends each profile \( a_{-J} \in A_{-J} \) to the other players \(-J\) with probability \( \frac{1}{|A_{-J}|} \). The state transitions as follows: if the current state is \( J \) and players \( J' \) deviate, then the state transitions to \( J \cup J' \).

Player \( i \)'s strategy is to follow her recommendation \( r_{i,t} \) in period \( t \). She believes that the mediator’s state is \( \emptyset \) if she herself has never deviated, and believes that the state is \( \{i\} \) if she has deviated.

Since the mediator’s recommendation has full support, player \( i \)'s belief is consistent. (In particular, no matter how many times player \( i \) has been instructed to minmax some player \( j \), it is always infinitely more likely that these instructions resulted from randomization by the mediator rather than a deviation by player \( j \).) If player \( i \) has deviated, then (given her belief) it is optimal for her to always play a static best response to \( \alpha_{-i}^{\varepsilon} \), since the mediator always recommends \( \alpha_{-i}^{\varepsilon} \) in state \( \{i\} \). Given that a unilateral deviation by player \( i \) is punished in this way, (1) implies that on path player \( i \) has a strict incentive to follow her recommendation \( r_{i,t} \) at any recommendation profile \( r_t \in A \). Hence, she has a strict incentive to follow her recommendation when she believes that \( r_{i,t} \) is distributed according to \( \Pr^\mu(r_{-i,t}|r_i^t) \).

The condition that \( W^* \neq \emptyset \) can be more transparently stated as a lower bound on the discount factor. In particular, \( W^* \neq \emptyset \) if and only if there exists \( v \in \mathcal{F} \) such that

\[
 v_i > u_i + \frac{1 - \delta}{\delta} d_i \quad \text{for all } i \in I,
\]

or equivalently

\[
 \delta > \delta^* \equiv \min_{v \in \mathcal{F}} \max_{i \in I} \frac{d_i}{d_i + v_i - u_i}.
\]

For instance, it can be checked that \( \delta^* = \frac{19}{25} \) in Example 1 of Section 3. Note that \( \delta^* \) is strictly less than 1 if and only if the stage game admits a feasible and strictly individually
rational payoff vector (relative to correlated minmax payoffs). For most games of interest, \( \delta^* \) will be some “intermediate” discount factor that is not especially close to either 0 or 1.

Our second preliminary result is that, if a strict full-support equilibrium exists, then any payoff vector that can be attained by a mediator’s strategy that is incentive compatible on path is (virtually) attainable in strict equilibrium.

**Lemma 2** With mediated perfect monitoring, fix a payoff vector \( v \), and suppose there exists a mediator’s strategy \( \mu \) that (1) attains \( v \) when players obey the mediator, and (2) has the property that obeying the mediator is optimal for each player at each on-path history, when she is minmaxed forever if she deviates: that is, for each player \( i \) and on-path history \( h_{m+1} \),

\[
(1 - \delta) \mathbb{E} \left[ u_i(r_t) \mid h_m, r_{i,t} \right] + \delta \mathbb{E} \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(\mu(h_{m}) \mid h_m, r_{i,t}) \right] \\
\geq \max_{a_i \in A_i}(1 - \delta) \mathbb{E} \left[ u_i(a_i, r_{-i,t}) \mid h_m, r_{i,t} \right] + \delta u_i.
\]

(3)

Suppose also that there exists a strict full-support equilibrium. (For example, such an equilibrium exists if \( \hat{W}^* \neq \emptyset \), by Lemma 1.) Then \( v \in \overline{E_{med}(\delta)} \).

**Proof.** Fix such a strategy \( \mu \) and any strict full-support equilibrium \( \mu^{\text{strict}} \). We construct a strict equilibrium that attains a payoff close to \( v \).

In period 1, the mediator draws one of two states, \( R_v \) and \( R_{\text{perturb}} \), with probabilities \( 1 - \varepsilon \) and \( \varepsilon \), respectively. In state \( R_v \), the mediator’s recommendation is determined as follows: If no player has deviated up to period \( t \), the mediator recommends \( r_t \) according to \( \mu(h^t_m) \). If only player \( i \) has deviated, the mediator recommends \( r_{-i,t} \) to players \( -i \) according to \( \alpha^{*}_{-i} \), and recommends some best response to \( \alpha^{*}_{-i} \) to player \( i \). Multiple deviations are treated as in the proof of Lemma 1. On the other hand, in state \( R_{\text{perturb}} \), the mediator follows the equilibrium \( \mu^{\text{strict}} \). Player \( i \) follows the recommendation \( r_{i,t} \) in period \( t \). Since the constructed recommendation schedule has full support, player \( i \) never believes that another player has deviated. Moreover, since \( \mu^{\text{strict}} \) has full support, player \( i \) believes that the mediator’s state is \( R_{\text{perturb}} \) with positive probability after any history. Therefore, by (3) and the fact that \( \mu^{\text{strict}} \) is a strict equilibrium, it is always strictly optimal for each player \( i \) to follow her

---

8 Recall that a payoff vector \( v \) is strictly individually rational if \( v_i > u_i \) for all \( i \in I \).

9 Throughout, \( \overline{X} \) denotes the closure of \( X \).
recommendation on path. Taking \( \varepsilon \to 0 \) yields a sequence of strict equilibria with payoffs converging to \( v \). ■

5 A Sufficient Condition for \( E_{\text{med}}(\delta) \) to Give an Upper Bound

Our sufficient condition for mediated perfect monitoring to outperform private monitoring in two-player games is that \( \delta > \delta^* \). In Section 9, we discuss what happens when there are more than two players or the condition that \( \delta > \delta^* \) is relaxed.

Let \( E(\delta, p) \) be the set of (possibly weak) sequential equilibrium payoffs with private monitoring structure \( p \). Note that \( E(\delta, p) \) is closed, as we use the product topology on assessments (Fudenberg and Levine, 1983).

**Theorem 1** If \(|I| = 2 \) and \( \delta > \delta^* \), then for every private monitoring structure \( p \) and every non-negative Pareto weight \( \lambda \in \Lambda_+ \equiv \{ \lambda \in \mathbb{R}^2_+ : \|\lambda\| = 1 \} \), we have

\[
\max_{v \in E(\delta, p)} \lambda \cdot v \leq \max_{v \in E_{\text{med}}(\delta)} \lambda \cdot v.
\]

Theorem 1 says that, in games involving two players of at least moderate patience, the Pareto frontier of the (closure of the strict) equilibrium payoff set with mediated perfect monitoring extends farther in any non-negative direction than does the Pareto frontier of the equilibrium payoff set with any private monitoring structure.\(^\text{10}\) We emphasize that Theorem 1 does not require that players are patient enough for the folk theorem to apply.

We describe the idea of the proof of Theorem 1, deferring the proof itself to Section 8.

Let \( \mathcal{E}(\delta) \) be the equilibrium payoff set in the mediated repeated game with the following **universal monitoring structure**: the mediator directly observes the recommendation profile \( r_t \) and the action profile \( a_t \) in each period \( t \), while each player \( i \) observes nothing beyond her own recommendation \( r_{i,t} \) and her own action \( a_{i,t} \).\(^\text{11}\) This monitoring structure is so called because it embeds any private monitoring structure \( p \) by setting \( \mu(h_{m_t}^i) \) equal to \( p(\cdot | a_{t-1}) \)

\(^\text{10}\)We do not know if the same result holds for negative Pareto weights.

\(^\text{11}\)This information structure may not result from mediated communication among the players, as actions are not publicly observed. Again, we simply view \( \mathcal{E}(\delta) \) as a technical device for bounding \( E(\delta, p) \).
for every history $h^t_m = (r^t, a^t)_{t=1}^{T-1}$.\textsuperscript{12} It particular, we have $E(\delta, p) \subseteq \mathcal{E}(\delta)$ for every $p$, so to prove Theorem 1 it suffices to show that

$$
\sup_{\lambda \in \mathcal{E}(\delta)} \lambda \cdot v \leq \max_{\lambda \in \mathcal{E}(\delta)} \lambda \cdot v. \quad (4)
$$

To show this, the idea is to start with an equilibrium in $\mathcal{E}(\delta)$—where players only observe their own recommendations—and then show that the players’ recommendations can be “publicized” without violating anyone’s obedience constraints.\textsuperscript{13} To see why this is possible (when $|I| = 2$ and $\delta > \delta^*$, or equivalently $\hat{W}^* \neq \emptyset$), first note that we can restrict attention to equilibria with Pareto-efficient on-path continuation payoffs, as improving both players’ on-path continuation payoffs improves their incentives (assuming that deviators are minmaxed, which is possible when $\hat{W}^* \neq \emptyset$, by Lemma 2). Next, if $|I| = 2$ and $\hat{W}^* \neq \emptyset$, then if a Pareto-efficient payoff vector $v$ lies outside $W_i$ for one player (say player 2), it must then lie inside $W_j$ for the other player (player 1). Hence, at each history $h^t$, there can be only one player—here player 2—whose obedience constraint could be violated if we publicized both players’ past recommendations.

Now, suppose that at history $h^t$ we do publicize the entire vector of players’ past recommendations $r^t = (r^t)_{t=1}^{T-1}$, but the mediator then issues period $t$ recommendations according to the original equilibrium distribution of recommendations conditional on player 2’s past recommendations $r^t_2 = (r^t_2)_{t=1}^{T-1}$ only. We claim that doing this violates neither player’s obedience constraint: Player 1’s obedience constraint is easy to satisfy, as we can always ensure that continuation payoffs lie in $W_1$. And, since player 2 already knew $r^t_2$ in the original equilibrium, publicizing $h^t$ while issuing recommendations based only on $r^t_2$ does not affect his incentives.

An important missing step in this proof sketch is that, in the original equilibrium in $\mathcal{E}(\delta)$, at some histories it may be player 1 who is tempted to deviate when we publicize past recommendations, while it is player 2 who is tempted at other histories. For instance, it is not obvious how to publicize past recommendations when ex ante equilibrium payoffs are very good for player 1 (so player 2 is tempted to deviate in period 1), but continuation

\textsuperscript{12}Incidentally, this embedding does not yield an obedient equilibrium.

\textsuperscript{13}More precisely, the construction in the proof both publicizes the players’ recommendations and modifies the equilibrium in ways that only improve the players’ $\lambda$-weighted payoffs.
payoffs at some later history are very good for player 2 (so then player 1 is tempted to deviate). The proof of Theorem 1 shows that we can ignore this possibility, because—somewhat unexpectedly—equilibrium paths like this one are never needed to sustain Pareto-efficient payoffs. In particular, to sustain an ex ante payoff that is very good for player 1 (i.e., outside $W_2$), we never need to promise continuation payoffs that are very good for player 2 (i.e., outside $W_1$). The intuition is that, rather than promising player 2 a very good continuation payoff outside $W_1$, we can instead promise him a fairly good continuation inside $W_1$, while compensating him for this change by also occasionally transitioning to this fairly good continuation payoff at histories where the original promised continuation payoff is less good for him. Finally, since the feasible payoff set is convex, the resulting “compromise” continuation payoff vector is also acceptable to player 1.

A remark: The reader may wonder why we are not satisfied with simply bounding $E(\delta, p)$ by $\mathcal{E}(\delta)$. The answer is that the only way we know of recursively characterizing the Pareto frontier of $\mathcal{E}(\delta)$ is by first establishing (4) and then characterizing the Pareto frontier of $\overline{E_{\text{med}}(\delta)}$. So this approach would not avoid the need to establish (4).

6 Recursively Characterizing $\overline{E_{\text{med}}(\delta)}$

We have seen that $\overline{E_{\text{med}}(\delta)}$ is an upper bound on $E(\delta, p)$ for two-player games satisfying $\delta > \delta^*$. As our goal is to give a recursive upper bound on $E(\delta, p)$, it remains to recursively characterize $\overline{E_{\text{med}}(\delta)}$. Our characterization assumes that $\delta > \delta^*$, but it applies for any number of players.\footnote{The set $\overline{E_{\text{med}}(\delta)}$ admits a recursive characterization even if $\delta < \delta^*$, but in this case the characterization is somewhat more complicated. The details are available from the authors.}

Recall that APS characterize the perfect public equilibrium set with imperfect public monitoring as the iterative limit of a generating operator $B$, where $B(W)$ is defined as the set of payoffs that can be sustained when on- and off-path continuation payoffs are drawn from $W$. We show that the sequential equilibrium payoff set with mediated perfect monitoring is the iterative limit of a generating operator $\tilde{B}$, where $\tilde{B}(W)$ is the set of payoffs that can be sustained when on-path continuation payoffs are drawn from $W$ and deviators are minmaxed off path. There are two things to prove: (1) we can indeed minmax deviators
off path, and (2) on-path continuation payoffs must themselves be sequential equilibrium payoffs. The first of these facts is Lemma 2. For the second, note that, in an obedient equilibrium with perfect monitoring, players can perfectly infer each other’s private history on path. Continuation play at on-path histories (but not off-path histories) is therefore “common knowledge,” which gives the desired recursive structure.

In what follows, we assume familiarity with APS and focus on the new features that emerge when mediation is available. Our terminology parallels that in Section 7.3 of Mailath and Samuelson (2006).

**Definition 2** For any set \( V \subseteq \mathbb{R}^I \), a correlated action profile \( \alpha \in \Delta (A) \) is minmax-threat enforceable on \( V \) by a mapping \( \gamma : A \to V \) if, for each player \( i \) and action \( a_i \in \text{supp} \alpha_i \),

\[
\mathbb{E}^\alpha [(1 - \delta) u_i (a_i, a_{-i}) + \delta \gamma (a_i, a_{-i}) \mid a_i] \geq \max_{a'_i \in A_i} \mathbb{E}^\alpha [(1 - \delta) u_i (a'_i, a_{-i}) \mid a_i] + \delta u_i.
\]

**Definition 3** A payoff vector \( v \in \mathbb{R}^I \) is minmax-threat decomposable on \( V \) if there exists a correlated action profile \( \alpha \in \Delta (A) \) which is minmax-threat enforced on \( V \) by a mapping \( \gamma \) such that

\[
v = \mathbb{E}^\alpha [(1 - \delta) u (a) + \delta \gamma (a)].
\]

Let \( \tilde{B} (V) = \{ v \in \mathbb{R}^I : v \text{ is minmax-threat decomposable on } V \} \).

We show that the following algorithm recursively computes \( \overline{E_{\text{med}}} (\delta) \): let \( W^1 = F, W^n = \tilde{B} (W^{n-1}) \) for \( n > 1 \), and \( W^\infty = \lim_{n \to \infty} W^n \).

**Theorem 2** If \( \delta > \delta^* \), then \( \overline{E_{\text{med}}} (\delta) = W^\infty \).

With the exception of the following two lemmas, the proof of Theorem 2 is entirely standard, and omitted. The lemmas correspond to facts (1) and (2) above. In particular, Lemma 3 follows directly from APS and Lemma 2, while Lemma 4 establishes on-path recursivity. For both lemmas, assume \( \delta > \delta^* \).

**Lemma 3** If a set \( V \subseteq \mathbb{R}^I \) is bounded and satisfies \( V \subseteq \tilde{B} (V) \), then \( \tilde{B} (V) \subseteq \overline{E_{\text{med}}} (\delta) \).

**Lemma 4** \( \overline{E_{\text{med}}} (\delta) = \tilde{B} \left( \overline{E_{\text{med}}} (\delta) \right) \).
**Proof.** By Lemma 3 and boundedness, we need only show that $\overline{E_{\text{med}}(\delta)} \subseteq \tilde{B}\left(\overline{E_{\text{med}}(\delta)}\right)$.

Let $E_{\text{med}}^\text{weak}(\delta)$ be the set of (possibly weak) sequential equilibrium payoffs with mediated perfect monitoring. Note that, in any sequential equilibrium, player $i$’s continuation payoff at any history $h^i_t$ must be at least $u_i$. Therefore, if $\mu$ is an on-path recommendation strategy in a (possibly weak) sequential equilibrium, then it must satisfy (3). Hence, under the assumption that $W^* \neq \emptyset$, we have $E_{\text{med}}^\text{weak}(\delta) \subseteq \overline{E_{\text{med}}(\delta)}$.

Now, for any $v \in E_{\text{med}}(\delta)$, let $\mu$ be a corresponding equilibrium mediator’s strategy. In the corresponding equilibrium, if some player $i$ deviates in period 1 while her opponents are obedient, player $i$’s continuation payoff must be at least $u_i$. Hence, we have

$$E_{\mu}^\mu [(1 - \delta) u_i (a_i, a_{-i}) + \delta w_i (a_i, a_{-i}) | a_i] \geq \max_{a_i' \in A_i} E_{\mu}^\mu [(1 - \delta) u_i (a_i', a_{-i}) | a_i] + \delta u_i,$$

where $w_i (a_i, a_{-i})$ is player $i$’s equilibrium continuation payoff when action profile $(a_i, a_{-i})$ is recommended and obeyed in period 1. Finally, since action profile $(a_i, a_{-i})$ is in the support of the mediator’s recommendation in period 1, each player assigns probability 1 to the true mediator’s history when $(a_i, a_{-i})$ is recommended and played in period 1. Therefore, continuation play from this history is itself at least a weak sequential equilibrium. In particular, we have $w_i (a_i, a_{-i}) \in E_{\text{med}}^\text{weak}(\delta) \subseteq \overline{E_{\text{med}}(\delta)}$ for all $(a_i, a_{-i}) \in \text{supp} \mu(h^i)$. Hence, $v$ is minmax-threat decomposable on $\overline{E_{\text{med}}(\delta)}$ by action profile $\mu(\emptyset)$ and continuation payoff function $w$, so in particular $v \in \tilde{B}\left(\overline{E_{\text{med}}(\delta)}\right)$.

We have shown that $E_{\text{med}}(\delta) \subseteq \tilde{B}\left(\overline{E_{\text{med}}(\delta)}\right)$. As $\overline{E_{\text{med}}(\delta)}$ is compact and $\tilde{B}$ preserves compactness, taking closures yields $\overline{E_{\text{med}}(\delta)} \subseteq \overline{\tilde{B}\left(\overline{E_{\text{med}}(\delta)}\right)} = \tilde{B}\left(\overline{E_{\text{med}}(\delta)}\right)$.

Combining Theorems 1 and 2 yields our main conclusion: *in two-player games with $\delta > \delta^*$, the equilibrium payoff set with mediated perfect monitoring is a recursive upper bound on the equilibrium payoff set with any imperfect private monitoring structure.*

### 7 The Upper Bound in an Example

We illustrate our results with an application to a repeated Bertrand game. We compute the greatest equilibrium payoff that each firm can attain for any private monitoring structure.

Consider the following Bertrand game: There are two firms $i \in \{1, 2\}$, and each firm $i$’s
possible price level is \( p_i \in \{W, L, M, H\} \) (price war, low price, medium price, high price).

Given \( p_1 \) and \( p_2 \), firm \( i \)'s profit is determined by the following payoff matrix:

\[
\begin{array}{cccc}
W & L & M & H \\
W & 15,15 & 30,25 & 50,15 & 80,0 \\
L & 25,30 & 40,40 & 60,35 & 90,15 \\
M & 15,50 & 35,60 & 55,55 & 85,35 \\
H & 0,80 & 15,90 & 35,85 & 65,65 \\
\end{array}
\]

Example 2

Note that \( L \) (low price) is a dominant strategy in the stage game, \( W \) (price war) is a costly action that hurts the other firm, and \( (H, H) \) maximizes the sum of the firms’ profits. The feasible payoff set is given by

\[
\mathcal{F} = \text{co} \{(0, 80), (15, 15), (15, 90), (35, 85), (65, 65), (80, 0), (85, 35), (90, 15)\},
\]

where we include only the extreme points in specifying the convex hull. In addition, each firm’s minmax payoff \( u_i \) is 25, so the feasible and individually rational payoff set is given by

\[
\text{co} \{(25, 25), (25, 87.5), (35, 85), (65, 65), (85, 35), (87.5, 25)\}.
\]

In particular, the greatest feasible and individually rational payoff for each firm is 87.5. See Figure 2 for an illustration.

In this game, each firm’s maximum deviation gain \( d_i \) is 25. Since the game is symmetric, the critical discount factor \( \delta^* \) above which we can apply Theorems 1 and 2 is given by

\[
\delta^* = \frac{25}{25 + 65 - 25} = \frac{5}{13}.
\]

To illustrate our results, we find the greatest equilibrium payoff that each firm can attain for any private monitoring structure when \( \delta = \frac{1}{2} > \frac{5}{13} \).
When $\delta = \frac{1}{2}$, we have
\[ w_i = 25 + \frac{1 - \delta}{\delta} 25 = 50. \]
Hence, Lemma 1 implies that
\[ \{ v \in \mathcal{F} : v_i > 50 \text{ for each } i \} = \text{int} \text{co} \{(50, 50), (75, 50), (50, 75), (65, 65)\} \subseteq \text{E}_{\text{med}}(\delta). \]

We now compute the best payoff vector for firm 1 in $\tilde{B}(\mathcal{F})$. By Theorems 1 and 2, any Pareto-efficient payoff profile not included $\tilde{B}(\mathcal{F})$ is not included in $E(\delta, p)$ for any $p$.

In computing the best payoff vector for firm 1, it is natural to conjecture that firm 1’s incentive compatibility constraint is not binding. We thus consider a relaxed problem with only firm 2’s incentive constraint, and then verify that firm 1’s incentive constraint is satisfied. Note that playing $L$ is always the best deviation for firm 2. Furthermore, the corresponding deviation gain decreases as firm 1 increases its price from $W$ to $L$, and (weakly) increases as it increases its price from $L$ to $M$ or $H$. On the other hand, firm 1’s payoff increases as firm 1 increases its price from $W$ to $L$ and decreases as it increases its price from $L$ to $M$ or $H$. Hence, in order to maximize firm 1’s payoff, firm 1 should play $L$.

Suppose that firm 2 plays $H$. Then, firm 2’s incentive compatibility constraint is
\[ (1 - \delta) \underbrace{25}_{\text{maximum deviation gain}} \leq \delta(\underbrace{w_2 - 25}_{\text{minmax payoff}}), \]
where $w_2$ is firm 2’s continuation payoff. That is, $w_2 \geq 50$.

By feasibility, $w_2 \geq 50$ implies that $w_1 \leq 75$. Hence, if $r_2 = H$, the best minmax-threat decomposable payoff for firm 1 is
\[ (1 - \delta) \begin{pmatrix} 90 \\ 15 \end{pmatrix} + \delta \begin{pmatrix} 75 \\ 50 \end{pmatrix} = \begin{pmatrix} 82.5 \\ 32.5 \end{pmatrix}. \]
Since 82.5 is larger than any payoff that firm 1 can get when firm 2 plays $W$, $M$, or $L$, firm 2 should indeed play $H$ to maximize firm 1’s payoff. Moreover, since $75 \geq w_1$, firm 1’s incentive constraint is not binding. Thus, we have shown that 82.5 is the best payoff for firm 1 in $\tilde{B}(\mathcal{F})$. 

20
Figure 2: Region A is included in $E_{\text{med}}(\delta)$ by Lemma 1. Region B is not included in $E_{\text{med}}(\delta)$. Note that Region B includes payoffs which are feasible and individually rational.

On the other hand, with mediated perfect monitoring it is in fact possible to (virtually) implement an action path in which firm 1’s payoff is 82.5: play $(L, H)$ in period 1 (with payoffs $(90, 15)$), and then play $\frac{1}{2}(M, H) + \frac{1}{2}(H, H)$ forever (with payoffs $\frac{1}{2}(85, 35) + \frac{1}{2}(65, 65) = (75, 50)$), while minmaxing deviators.

Thus, when $\delta = \frac{1}{2}$, each firm’s greatest feasible and individually rational payoff is 87.5, but the greatest payoff it can attain with any imperfect private monitoring structure is only 82.5. In this simple game, we can therefore say exactly how much of a constraint is imposed on each firm’s greatest equilibrium payoff by the firms’ impatience alone, independently of the monitoring structure.

8 Proof of Theorem 1

8.1 Preliminaries and Plan of Proof

We wish to establish (4) for every Pareto weight $\lambda \in \Lambda_+$. As $E(\delta)$ is convex, it suffices to establish

$$
\max_{v \in E_0(\delta)} \lambda \cdot v \leq \max_{v \in E_{\text{med}}(\delta)} \lambda \cdot v
$$

(5)
for every compact set $E_0(\delta) \subseteq E(\delta)$.

Fix a compact set $E_0(\delta) \subseteq E(\delta)$. Note that Lemma 1 implies that

$$W^* \subseteq E_{\text{med}}(\delta).$$

Therefore, for every Pareto weight $\lambda \in \Lambda_+$, if there exists $v \in \arg \max_{v' \in E_0(\delta)} \lambda \cdot v'$ such that $v \in W^*$, then there exists $v^* \in E_{\text{med}}(\delta)$ such that $\lambda \cdot v \leq \lambda \cdot v^*$, as desired.

Hence, we are left to consider $\lambda \in \Lambda_+$ with

$$\arg \max_{v' \in E_0(\delta)} \lambda \cdot v' \cap W^* = \emptyset. \quad (6)$$

Since we consider two-player games, we can order $\lambda \in \Lambda_+$ as follows: $\lambda \leq \lambda'$ if and only if $\frac{\lambda_1}{\lambda_2} \leq \frac{\lambda'_1}{\lambda'_2}$, that is, the vector $\lambda$ is steeper than $\lambda'$. For each player $i$, let $\bar{w}^i$ be the Pareto-efficient point in $W_i$ satisfying

$$\bar{w}^i \in \arg \max_{v \in W_i \cap F} v_{-i}.$$ 

Note that the assumption that $\bar{W}^* \neq \emptyset$ implies that $\bar{w}^i \in W^*$. Let $\alpha^i \in \Delta(A)$ be a recommendation that attains $\bar{w}^i$: $u(\alpha^i) = \bar{w}^i$. Let $\Lambda^i$ be the (non-empty) set of Pareto weight $\lambda^i$ such that $\bar{w}^i \in \arg \max_{v \in F} \lambda^i \cdot v$:

$$\Lambda^i = \left\{ \lambda^i \in \mathbb{R}^2_+ : \|\lambda^i\| = 1, \bar{w}^i \in \arg \max_{v \in F} \lambda^i \cdot v \right\}.$$

As $F$ is convex, if $\lambda$ satisfies (6) then either $\lambda < \lambda^1$ for each $\lambda^1 \in \Lambda^1$ or $\lambda > \lambda^2$ for each $\lambda^2 \in \Lambda^2$. See Figure 3. We focus on the case where $\lambda > \lambda^2$. (The proof for the $\lambda < \lambda^1$ case is symmetric and thus omitted.)

Fix $v \in \arg \max_{v' \in E_0(\delta)} \lambda \cdot v'$. Let $(\mu, (\sigma_i)_{i \in I})$ be an equilibrium that attains $v$ with the universal monitoring structure (where players do not observe each other’s actions). By Lemma 2, it suffices to construct a mediator’s strategy $\mu^*$ yielding payoffs $v^*$ such that (3) (“perfect monitoring incentive compatibility”) holds and $\lambda \cdot v \leq \lambda \cdot v^*$. The rest of the proof constructs such a strategy.

The plan for constructing the strategy $\mu^*$ is as follows: First, from $\mu$ we construct a mediator’s strategy $\bar{\mu}$ that yields payoffs $v$ and satisfies perfect monitoring incentive com-
Figure 3: Setup for the construction. The green region (intersection of $u(A)$, $W_1$, and $W_2$) is included in $E_{\text{med}}(\delta)$ and $E(\delta)$ by Lemma 1. The red line represents $E(\delta)$.

compatibility for player 2, but possibly not for player 1. The idea is to set the distribution of recommendations under $\bar{\mu}$ equal to the distribution of recommendations under $\mu$ conditional on player 2’s information only. Second, from $\bar{\mu}$, we construct a mediator’s strategy $\mu^*$ that yields payoffs $v^*$ with $\lambda \cdot v \leq \lambda \cdot v^*$ and satisfies perfect monitoring incentive compatibility for both players.

8.2 Construction and Properties of $\bar{\mu}$

For each on-path history of player 2’s recommendations, denoted by $r^t_2 = (r_{2,t})_{t=1}^{t-1}$ (with $r^1_2 = \emptyset$), let $\Pr^\mu(\cdot | r^t_2)$ be the conditional distribution of recommendations in period $t$, and let $w^\mu(r^t_2)$ be the continuation payoff vector from period $t$ onward conditional on $r^t_2$:

$$w^\mu(r^t_2) = \mathbb{E}^\mu \left[ \sum_{\tau=0}^{\infty} \delta^\tau u(r_{t+\tau}) \mid r^t_2 \right].$$

Define $\bar{\mu}$ so that, for every on-path history $r^t = (r_{\tau})_{\tau=1}^{t-1}$ (with $r^1 = \emptyset$), the mediator draws $r_t$ according to $\Pr^\mu(r_t | r^t_2)$:

$$\Pr^{\bar{\mu}}(r_t | r^t) \equiv \Pr^\mu(r_t | r^t_2). \quad (7)$$
We claim that $\bar{\mu}$ yields payoffs $v$ and satisfies (3) for player 2. To see this, let $w^\mu(r^t)$ be the continuation payoff vector from period $t$ onward conditional on $r^t$ under $\bar{\mu}$, and note that $w^\mu(r^t) = w^\mu(r_2^t)$. In particular, $w^\mu(r^1) = w^\mu(r_2^1) = v$ since $r^1 = r_2^1 = \emptyset$. In addition, the fact that $\mu$ is an equilibrium with the universal monitoring structure implies that, for every on-path history $r^{t+1}$,

$$(1 - \delta) \mathbb{E}^{\mu} [u_2 (r_t) | r_2^{t+1}] + \delta w^\mu (r_2^{t+1}) \geq \max_{a_2 \in A_2} (1 - \delta) \mathbb{E}^{\mu} [u_2 (r_{1,t}, a_2) | r_2^{t+1}] + \delta w_2.$$

As $w_2^\mu(r_2^{t+1}) = w_2^\bar{\mu}(r_2^{t+1})$ and $\Pr^\mu(r_t | r_2^{t+1}) = \Pr^\bar{\mu}(r_t | r^t, r_2, t)$, this implies that (3) holds for player 2.

### 8.3 Construction of $\mu^*$

The mediator’s strategy $\mu^*$ will involve mixing over continuation payoffs at certain histories $r^{t+1}$, and we will denote the mixing probability at history $r^{t+1}$ by $\rho(r^{t+1})$. Our approach is to first construct the mediator’s strategy $\mu^*$ for an arbitrary function $\rho : \bigcup_{t=1}^{\infty} A^{t-1} \to [0, 1]$ specifying these mixing probabilities, and to then specify the function $\rho$.

Given a function $\rho : \bigcup_{t=1}^{\infty} A^{t-1} \to [0, 1]$, the mediator’s strategy $\mu^*$ is defined as follows: In each period $t = 0, 1, 2, \ldots$, the mediator is in one of two states, $\omega_t \in \{S_1, S_2\}$ (where “period 0” is a purely notational, and as usual the game begins in period 1). Given the state, recommendations in period $t \geq 1$ are as follows:

1. In state $S_1$, at history $r^t = (r_\tau)_{\tau=1}^{t-1}$, the mediator recommends $r_t$ according to $\Pr^\bar{\mu}(r_t | r^t)$.

2. In state $S_2$, the mediator recommends $r_t$ according to some $\alpha^1 \in \Delta(A)$ such that $u(\alpha^1) = \bar{w}^1$.

The initial state is $\omega_0 = S_1$. State $S_2$ is absorbing: if $\omega_t = S_2$ then $\omega_{t+1} = S_2$. Finally, the transition rule in state $S_1$ is as follows:

1. If $w^\bar{\mu}(r^{t+1}) \notin W_1$, then $\omega_{t+1} = S_2$ with probability one.

2. If $w^\bar{\mu}(r^{t+1}) \in W_1$, then $\omega_{t+1} = S_2$ with probability $1 - \rho(r^{t+1})$. 

24
Thus, strategy $\mu^*$ agrees with $\bar{\mu}$, with the exception that $\mu^*$ occasionally transitions to an absorbing state where actions yielding payoffs $\bar{w}^1$ are recommended forever. In particular, such a transition always occurs when continuation payoffs under $\bar{\mu}$ lie outside $W_1$, and otherwise this transition occurs with probability $1 - \rho(r^{t+1})$.

To complete the construction of $\mu^*$, it remains only to specify the function $\rho$. To this end, it is useful to define an operator $F$, which maps functions \( w : \bigcup_{t=1}^{\infty} A^{t-1} \to \mathbb{R}^2 \) to functions \( F(w_2) : \bigcup_{t=1}^{\infty} A^{t-1} \to \mathbb{R}^2 \). The operator $F$ will be defined so that its unique fixed point is precisely the continuation value function in state $S_1$ under $\mu^*$ for a particular function $\rho$, and this function will be the one we use to complete the construction of $\mu^*$.

Given $w : \bigcup_{t=1}^{\infty} A^{t-1} \to \mathbb{R}^2$, define $w^*(w) : \bigcup_{t=1}^{\infty} A^{t-1} \to \mathbb{R}$ so that, for every $r^t \in A^{t-1}$, we have

\[
w^*(w)(r^t) = (1 - \delta) u \left( \bar{\mu}(r^t) \right) + \delta \mathbb{E} \left[ w(r^{t+1} | r^t) \right].
\]

On the other hand, given $w^*(w) : \bigcup_{t=1}^{\infty} A^{t-1} \to \mathbb{R}$, define $F(w) : \bigcup_{t=1}^{\infty} A^{t-1} \to \mathbb{R}$ so that, for every $r^t \in A^{t-1}$, we have

\[
F(w)(r^t) = 1_{\{w^*(r^t) \in W_1\}} \left\{ \begin{array}{l}
\rho(w)(r^t) \times w^*(w)(r^t) \\
+ (1 - \rho(w)(r^t)) \times \bar{w}^1
\end{array} \right\} + 1_{\{w^*(r^t) \notin W_1\}} \bar{w}^1,
\]

where, when $w^*(r^t) \in W_1$, $\rho(w)(r^t)$ is the largest number in $[0, 1]$ such that

\[
\rho(w)(r^t) \times w^*_2(w)(r^t) + (1 - \rho(w)(r^t)) \times \bar{w}^1 \geq w^\#_2(r^t).
\]

That is, if $w^*_2(w)(r^t) \geq w^\#_2(r^t)$ then $\rho(w)(r^t) = 1$; and otherwise, since $w^\#(r^t) \in W_1$ implies that $w^\#_2(r^t) \leq \bar{w}^1_2$, $\rho(w)(r^t) \in [0, 1]$ solves

\[
\rho(w)(r^t) \times w^*_2(w)(r^t) + (1 - \rho(w)(r^t)) \times \bar{w}^1_2 = w^\#_2(r^t).
\]

(Intuitively, the term $1_{\{w^*(r^t) \notin W_1\}} \bar{w}^1$ in (9) reflects the fact that we have replaced continuation payoffs outside of $W_1$ with player 2's most favorable continuation payoff within $W_1$, namely $\bar{w}^1$. This replacement may reduce player 2’s value below his original value of $w^\#_2(r^t)$. However, (10) ensures that, by also replacing continuation payoffs within $W_1$ with $\bar{w}^1$ with
high enough probability, player 2’s value does not fall below $w_2^0(r^t).$

To show that $F$ has a unique fixed point, it suffices to show that $F$ is a contraction.

**Lemma 5** For all $w$ and $\tilde{w}$, we have $\|F(w) - F(\tilde{w})\| \leq \delta \|w - \tilde{w}\|$, where $\|w - \tilde{w}\| \equiv \sup_{r,t} \|w(r^t) - \tilde{w}(r^t)\|.$

**Proof.** By (8), $\|w^*(w) - w^*(\tilde{w})\| \leq \delta \|w - \tilde{w}\|$. By (9),

$$|F(w)(r^t) - F(\tilde{w})(r^t)| = 1_{\{w^0(r^t) \in W_1\}} \left\{ \rho(w)(r^t)w^*(w)(r^t) + (1 - \rho(w)(r^t)) \tilde{w}^1 \right\} - \left\{ \rho(\tilde{w})(r^t)w^*(\tilde{w})(r^t) + (1 - \rho(\tilde{w})(r^t)) \tilde{w}^1 \right\} \leq \|w^*(w) - w^*(\tilde{w})\|.$$

Combining these inequalities yields $\|F(w) - F(\tilde{w})\| \leq \delta \|w - \tilde{w}\|$. \quad \blacksquare

Let $w$ be the unique fixed point of $F$. Given this function $w$, let $w^* = w^*(w)$ (given by (8)) and let $\rho = \rho(w)$ (given by (10)). This completes the construction of the mediator’s strategy $\mu^*$.

### 8.4 Properties of $\mu^*$

Observe that

$$w^*(r^t) = (1 - \delta) u(\bar{\mu}(r^t)) + \delta \mathbb{E} \left[ w(r^{t+1}) \right]$$

and

$$w(r^t) = 1_{\{w^0(r^t) \in W_1\}} \left\{ \rho(r^t)w^*(r^t) + (1 - \rho(r^t)) \tilde{w}^1 \right\} + 1_{\{w^0(r^t) \notin W_1\}} \tilde{w}^1.$$ 

Thus, for $i = 1, 2$, $w^*_i(r^t)$ is player $i$’s expected continuation payoff from period $t$ given $r^t$ and $\omega_t = S_1$ (before she observes $r_{i,t}$), and $w_i(r^t)$ is player $i$’s expected continuation payoff from period $t$ given $r^t$ and $\omega_{t-1} = S_1$ (before she observes $r_{i,t}$). In particular, recalling that $\omega_1 = S_1$ and $v = w^\mu(\emptyset) \in W_1$, (10) implies that the ex ante payoff vector $v^*$ is given by

$$v^* = w(\emptyset) = \rho(\emptyset)w^*(\emptyset) + (1 - \rho(\emptyset)) \tilde{w}^1.$$

We prove the following key lemma in Appendix 10.
Figure 4: The vector from \( w^\beta(r^t) \) to \( w^*(r^t) \) is parallel to the one from \( \tilde{w}(r^{t+1}) \) to \( \tilde{w}^1 \).

**Lemma 6** For all \( t \geq 1 \), if \( w^\beta(r^t) \in W_1 \), then \( \rho(r^t)w^*(r^t) + (1 - \rho(r^t)) \tilde{w}^1 \) Pareto dominates \( w^\beta(r^t) \).

Here is a graphical explanation of Lemma 6: By (11), \( w^*(r^t) - w^\beta(r^t) \) is parallel to \( w(r^{t+1}) - w^\beta(r^{t+1}) \). To evaluate this difference, consider (12) for period \( t + 1 \). The term \( \mathbb{1}_{\{w^\beta(r^{t+1}) \in W_1\}} \tilde{w}^1 \) indicates that we construct \( w(r^{t+1}) \) by replacing some continuation payoff not included in \( W_1 \) with \( \tilde{w}^1 \). Hence, \( w(r^{t+1}) - w^\beta(r^{t+1}) \) (and thus \( w^*(r^t) - w^\beta(r^t) \)) is parallel to \( \tilde{w}^1 - \tilde{w}(r^{t+1}) \) for some \( \tilde{w}(r^{t+1}) \in \mathcal{F} \setminus W_1 \). See Figure 4 for an illustration.

Recall that \( \rho(r^t) \) is determined by (10). Since the vector \( w^*(r^t) - w^\beta(r^t) \) is parallel to \( \tilde{w}^1 - \tilde{w}(r^{t+1}) \) for some \( \tilde{w}(r^{t+1}) \in \mathcal{F} \setminus W_1 \) and \( \mathcal{F} \) is convex, we have \( w^*_1(r^t) \geq w^\beta_1(r^t) \). Hence, if we take \( \rho(r^t) \) so that the convex combination of \( w^*_2(r^t) \) and \( \tilde{w}^1 \) is equal to \( w^\beta_2(r^t) \), then player 1 is better off compared to \( w^\beta_1(r^t) \). See Figure 5.

Given Lemma 6, we show that \( \mu^* \) satisfies perfect monitoring incentive compatibility ((3)) for both players, and \( \lambda \cdot v \leq \lambda \cdot v^* \).

1. Incentive compatibility for player 1: It suffices to show that, conditional on any on-path history \( r^t \) and period \( t \) recommendation \( r_{1,t} \), the expected continuation payoff from period \( t + 1 \) onward lies in \( W_1 \). If \( \omega_t = S_2 \), then this continuation payoff is \( \tilde{w}^1 \in W_1 \). If \( \omega_t = S_1 \), then it suffices to show that \( w(r^{t+1}) \in W_1 \) for all \( r^{t+1} \). If \( w^\beta(r^{t+1}) \in W_1 \), then, by Lemma 6, \( w(r^{t+1}) = \rho(r^{t+1})w^*(r^{t+1}) + (1 - \rho(r^{t+1})) \tilde{w}^1 \) Pareto dominates
Figure 5: $\rho(r^t)w^*(r^t) + (1 - \rho(r^t))\bar{w}^1$ and $w^\mu(r^t)$ have the same value for player 2.

$w^\mu(r^{t+1}) \in W_1$, so $w(r^{t+1}) \in W_1$. If $w^\mu(r^{t+1}) \notin W_1$, then $w(r^{t+1}) = \bar{w}^1 \in W_1$. Hence, $w(r^{t+1}) \in W_1$ for all $r^{t+1}$.

2. Incentive compatibility for player 2: Fix an on-path history $r^t$ and a period $t$ recommendation $r_{2,t}$. If $\omega_t = S_2$, or if both $\omega_t = S_1$ and $w^\mu(r^{t+1}) \notin W_1$, then the expected continuation payoff from period $t + 1$ onward conditional on $(r^t, r_{2,t})$ is $\bar{w}^1 \in W_1$, so (3) holds. If instead $\omega_t = S_1$ and $w^\mu(r^{t+1}) \in W_1$, then $w(r^{t+1}) = \rho(r^{t+1})w^*(r^{t+1}) + (1 - \rho(r^{t+1}))\bar{w}^1 = w^\mu(r^{t+1})$ by (10). As $\mu$ is an equilibrium with the universal monitoring structure and $Pr^\mu(r^t | r_{2,t}) = Pr^\mu(r^t | r_{2,t})$, this implies that (3) holds for player 2, by the same argument as in Section 8.2.

3. $\lambda \cdot v \leq \lambda \cdot v^*$: Immediate from Lemma 6 with $t = 1$.

9 Extensions

This section discusses the extent to which the payoff bound is tight, as well as what happens when the conditions for Theorem 1 are violated.
9.1 Tightness of the Bound

There are at least two senses in which $E_{\text{med}}(\delta)$ is a tight bound on the equilibrium payoff set, from the perspective of an observer who does not know the monitoring structure.

First, thus far our model of repeated games with private monitoring has maintained the standard assumption that the distribution of period $t$ signals depends only on period $t$ actions: that is, that this distribution can be written as $p(\cdot | a_t)$. In many settings, it would be desirable to relax this assumption and let the distribution of period $t$ signals depend on the entire history of actions and signals up to period $t$, leading to a conditional distribution of the form $p_t(\cdot | a_t^t, z^t)$, as well as letting players receive signals before the first round of play. (Recall that $a_t^t = (a_t^r)^{t-1}_{r=1}$ and $z_t^t = (z_t^r)^{t-1}_{r=1}$.) For example, colluding firms do not only observe their sales in every period, but also occasionally get more information about their competitors’ past behavior from trade associations, auditors, tax data, and the like.\textsuperscript{15} From the perspective of an observer who finds such nonstationary private monitoring structures possible, the bound $E_{\text{med}}(\delta)$ is clearly tight: $E_{\text{med}}(\delta)$ is an upper bound on $E(\delta, p)$ for any non-stationary private monitoring structure $p$, because the equilibrium payoff set with the universal monitoring structure, $E(\delta)$, remains an upper bound on $E(\delta, p)$; and the bound is tight because perfect monitoring with a given strategy of the mediator’s itself induces a particular nonstationary private monitoring structure.

Second, from the perspective of an observer who finds only stationary monitoring structures possible, the bound $E_{\text{med}}(\delta)$ is tight if the players can communicate through cheap talk, as they can then “replicate” the mediator among themselves. For this result, we also need to slightly generalize our definition of a private monitoring structure by letting the players receive signals before the first round of play, so that these signals can be used as a correlating device. This seems innocuous, especially if we take the perspective of an outside observer who does not know the game’s start date. The monitoring structure is required to be stationary thereafter.\textsuperscript{16} We call such a monitoring structure a private monitoring structure with ex ante correlation. Let $E_{\text{talk}}(\delta, p)$ be the sequential equilibrium payoff set in the repeated

\textsuperscript{15} Rahman (2014, p. 1) quotes from the European Commission decision on the amino acid cartel: a typical cartel member “reported its citric acid sales every month to a trade association, and every year, Swiss accountants audited those figures.”

\textsuperscript{16} In particular, the distribution of signals can be the same every period. All we require is that the first of these signals arrives before the first round of play.
game with private monitoring structure with ex ante correlation \( p \) and finitely many rounds of public cheap talk before each round of play.

**Proposition 2** If \(|I| = 2\) and \(\delta > \delta^*\), then there exists a private monitoring structure with ex ante correlation \( p \) such that \( \overline{E}_{\text{talk}}(\delta, p) = \overline{E}_{\text{med}}(\delta) \).

The proof is long and is deferred to the online appendix. The main idea is as in the literature on implementing correlated equilibria without a mediator (see Forges (2009) for a survey). More specifically, Proposition 2 is similar to Theorem 9 of Heller, Solan, and Tomala (2012), which shows that communication equilibria in repeated games with perfect monitoring can always be implemented by ex ante correlation and cheap talk. Since we also assume players observe actions perfectly, the main difference between the results is that theirs is for Nash rather than sequential equilibrium, so they are concerned only with detecting deviations rather than providing incentives to punish deviations once detected. In our model, when \(\delta > \delta^*\), incentives to minmax the deviator can be provided (as in Lemma 1) if her opponent does not realize that the punishment phase has begun. The additional challenge in the proof of Proposition 2 is thus that we sometimes need a player to switch to the punishment phase for her opponent without realizing that this switch has occurred.

If one insists on stationary monitoring and does not allow communication, we believe that there are some games in which our bound is not tight, in that there are points in \( \overline{E}_{\text{med}}(\delta) \) which are not attainable in equilibrium for any stationary private monitoring structure. We leave this as a conjecture.\(^{17}\)

### 9.2 What if \(\overline{W}^* = \emptyset\)?

The assumption that \(\overline{W}^* \neq \emptyset\) guarantees that all action profiles are supportable in equilibrium, which plays a key role in our results. However, this assumption is restrictive, in that it is violated when players are too impatient. Furthermore, it implies that the Pareto frontier of \( \overline{E}_{\text{med}}(\delta) \) coincides with the Pareto frontier of the feasible payoff set for some Pareto weights

\(^{17}\)Strictly speaking, since our maintained definition of a private monitoring structure does not allow ex ante correlation, if \(\delta = 0\) then there are points in \( \overline{E}_{\text{med}}(\delta) \) which are not attainable with any private monitoring structure whenever the stage game’s correlated equilibrium payoff set strictly contains its Nash equilibrium payoff set. The non-trivial conjecture is that the bound is still not tight when ex ante correlation is allowed, but communication is not.
\( \lambda \) (but of course not for others), so this assumption must also be relaxed for our approach to be able to give non-trivial payoff bounds for all Pareto weights.

To address these concerns, this subsection shows that even if \( \tilde{W}^* = \emptyset \), \( \overline{E}_{\text{med}}(\delta) \) may still be an upper bound on \( E(\delta, p) \) for any private monitoring structure \( p \), and \( \overline{E}_{\text{med}}(\delta) \) can still be characterized recursively. The idea is that, even if not all action profiles are supportable, our approach still applies if a condition analogous to \( \tilde{W}^* \neq \emptyset \) holds with respect to the subset of action profiles that are supportable.

Let \( \text{supp}(\delta) \) be the set of supportable actions with the universal monitoring structure:

\[
\text{supp}(\delta) = \left\{ a \in A : \begin{array}{c}
\text{with the universal monitoring structure,} \\
\text{there exist an equilibrium strategy } \mu \\
\text{and history } h^t_m \text{ with } a \in \text{supp}(\mu(h^t_m))
\end{array} \right\}.
\]

Note that in this definition \( h^t_m \) can be an off-path history.

On the other hand, given a product set of action profiles \( \bar{A} = \prod_{i \in I} \bar{A}_i \subseteq A \), let \( S_i(\bar{A}) \) be the set of actions \( a_i \in \bar{A}_i \) such that there exists a correlated action \( \alpha_{-i} \in \Delta(\bar{A}_{-i}) \) with

\[
(1 - \delta) u_i(a_i, \alpha_{-i}) + \delta \max_{\bar{a} \in \bar{A}} u_i(\bar{a}) \geq (1 - \delta) \max_{a_i \in A_i} u_i(\hat{a}_i, \alpha_{-i}) + \delta \min_{\hat{a}_{-i} \in \Delta(\bar{A}_{-i})} \max_{a_i \in A_i} u_i(a_i, \hat{a}_{-i}).
\]

That is, \( a_i \in S_i(\bar{A}) \) if there exists \( \alpha_{-i} \in \Delta(\bar{A}_{-i}) \) such that, if her opponents play \( \alpha_{-i} \), player \( i \)'s reward for playing \( a_i \) is the best payoff possible among those with support in \( \bar{A} \), and player \( i \)'s punishment for deviating from \( a_i \) is the worst possible among those with support in \( \bar{A}_{-i} \), then player \( i \) plays \( a_i \).

Let \( S(\bar{A}) = \prod_{i \in I} S_i(\bar{A}_i) \subseteq A \). Let \( A^1 = A \), let \( A^n = S(A^{n-1}) \) for \( n > 1 \), and let \( A^\infty = \lim_{n \to \infty} A^n \). Note that the problem of computing \( A^\infty \) is tractable, as the set \( S(\bar{A}) \) is defined by a finite number of linear inequalities.

Finally, in analogy with the definition of \( w_i \) from Section 4, note that

\[
\min_{\alpha_{-i} \in \Delta(A^\infty)} \max_{a_i \in A_i} u_i(a_i, \alpha_{-i}) + \frac{1 - \delta}{\delta} \max_{r \in A^\infty, a_i \in A_i} \{u_i(a_i, r_{-i}) - u_i(r)\}
\]

is the lowest continuation payoff such that player \( i \) does not want to deviate to any \( a_i \in A_i \) at any recommendation profile \( r \in A^\infty \), when she is minmaxed forever if she deviates, subject
to the constraint that punishments are drawn from $A^\infty$. In analogy with the definition of $W_i$ from Section 4, let

$$
\bar{W}_i = \left\{ w \in \mathbb{R}^{|I|} : w_i \geq \min_{a_{-i} \in \Delta(A^\infty)} \max_{a_i \in A_i} u_i(a_i, a_{-i}) + \frac{1 - \delta}{\delta} \max_{r \in A^\infty, a_i \in A_i} \left\{ u_i(a_i, r_{-i}) - u_i(r) \right\} \right\}.
$$

**Proposition 3** Assume that $|I| = 2$. If

$$\text{int} \left( \bigcap_{i \in I} W_i \cap \text{cou} (A^\infty) \right) \neq \emptyset \tag{14}$$

in the topology induced from $\text{cou} (A^\infty)$, then for every private monitoring structure $p$ and every non-negative Pareto weight $\lambda \in \Lambda_+$, we have

$$\max_{\nu \in E(\delta, p)} \lambda \cdot \nu \leq \max_{\nu \in E_{\text{med}}(\delta)} \lambda \cdot \nu.$$

In addition, $\text{supp}(\delta) = A^\infty$.

**Proof.** We show that $\text{supp}(\delta) = A^\infty$ whenever $\text{int} \left( \bigcap_{i \in I} W_i \cap \text{cou} (A^\infty) \right) \neq \emptyset$. Given this, the proof is analogous to the proof of Theorem 1, everywhere replacing $\mathcal{F} = \text{cou} (A)$ with $\text{cou} (A^\infty)$ and replacing “full support” with “full support within $A^\infty$.”

We first show that $\text{supp}(\delta) \subseteq A^\infty$. For each $i$ and $n$, we show that any action $a_i \notin A_i^n$ can never be played on or off the equilibrium path. The proof is by induction on $n$. The $n = 1$ case is trivial. Suppose the result holds for some $n$. Then at any history player $i$’s continuation payoff must lie between $\min_{\alpha_{-i} \in \Delta(A^n_i)} \max_{a_i \in A_i} u_i(a_i, \alpha_{-i})$ and $\max_{a \in A^n} u_i(a)$. Hence, player $i$ will never play an action $a_i$ for which there is no $\alpha_{-i} \in \Delta(A^n)$ with

$$(1 - \delta) u_i(a_i, \alpha_{-i}) + \delta \max_{a \in A^n} u_i(a) \geq (1 - \delta) \max_{\hat{a}_i \in A_i} u_i(\hat{a}_i, \alpha_{-i}) + \delta \min_{\hat{\alpha}_{-i} \in \Delta(A^n)} \max_{a_i \in A_i} u_i(a_i, \hat{\alpha}_{-i}).$$

This says that player $i$ will never play an action $a_i \notin A_i^{n+1}$.

We now show that if $\text{int} \left( \bigcap_{i \in I} W_i \cap \text{cou} (A^\infty) \right) \neq \emptyset$ then $A^\infty \subseteq \text{supp}(\delta)$. The argument is similar to the proof of Lemma 1.

Fix $\nu \in \text{int} \left( \bigcap_{i \in I} W_i \cap \text{cou} (A^\infty) \right) \neq \emptyset$, and let $\mu \in \Delta(A^\infty)$ be such that $u(\mu) = \nu$ and $\mu(r) > 0$ for all $r \in A^\infty$. Let $\alpha^*_i$ be a solution to the problem $\min_{\hat{\alpha}_{-i} \in \Delta(A^\infty)} \max_{a_i \in A_i} u_i(\hat{a}_i, \alpha_{-i})$. 32
Let $\alpha_{-i}^\varepsilon$ be the following full-support (within $A^\infty$) approximation of $\alpha_{-i}^*$: $\alpha_{-i}^\varepsilon = (1 - \varepsilon) \alpha_{-i}^* + \varepsilon \sum_{a_{-i} \in A_{-i}^\infty} \frac{a_{-i}}{|A_{-i}^\infty|}$. Since $v \in \text{int}(\bigcap_{i \in I} \hat{W}_i)$, there exists $\varepsilon > 0$ such that, for each $i \in I$, we have

\[ v_i > \max_{a_i \in A_i} u_i (a_i, \alpha_{-i}^\varepsilon) + \frac{1 - \delta}{\delta} \max_{r \in A^\infty, a_i \in A_i} \{ u_i (a_i, r_{-i}) - u_i (r) \} \tag{15} \]

Fix $\varepsilon > 0$ small enough such that, for each player $i$, some best response to $\alpha_{-i}^\varepsilon$ is included in $A_i^\infty$: this is always possible, as every best response to $\alpha_{-i}^*$ is included in $A_i^\infty$.

We can now construct an equilibrium strategy $\mu^*$ with $\text{supp} (\mu^* (\emptyset)) = A^\infty$. The construction is similar to that in the proof of Lemma 1, with the following differences. First, $\mu$ is recommended on path, and player $i$’s deviations are punished by recommending $\alpha_{-i}^\varepsilon$ to her opponents. Second, if a player deviates to an action outside $A^\infty$, play reverts to an arbitrary static Nash equilibrium $\alpha^{NE}$ forever.

Incentive compatibility with respect to deviations within $A^\infty$ follows from (15), just as it follows from (1) in the proof of Lemma 1. For incentive compatibility with respect to deviations outside $A^\infty$, fix $\hat{a}_i \notin A_i^\infty$ and $\alpha_{-i} \in \Delta (A_{-i}^\infty)$. Note that all static Nash equilibria are contained in $\Delta (A^\infty)$ and all static best responses to $\alpha_{-i}$ are contained in $A_i^\infty$. Therefore,

\[
(1 - \delta) u_i (\hat{a}_i, \alpha_{-i}) + \delta u_i (\alpha^{NE}) \leq (1 - \delta) u_i (\hat{a}_i, \alpha_{-i}) + \delta \max_{a \in A^\infty} u_i (a) \\
\quad < (1 - \delta) \max_{\hat{a}_i \in A_i} u_i (\hat{a}_i, \alpha_{-i}) + \delta \min_{\hat{a}_{-i} \in \Delta (A_{-i}^\infty)} \max_{a_i \in A_i} u_i (a_i, \hat{a}_{-i}) \\
\quad \quad \quad (\text{since } \hat{a}_i \notin A_i^\infty) \\
\quad = (1 - \delta) \max_{\hat{a}_i \in A_i^\infty} u_i (\hat{a}_i, \alpha_{-i}) + \delta \min_{\hat{a}_{-i} \in \Delta (A_{-i}^\infty)} \max_{a_i \in A_i} u_i (a_i, \hat{a}_{-i}).
\]

The last line corresponds to the deviation gain to some action $\hat{a}_i \in A_i^\infty$, which is not profitable. Hence, deviating to $\hat{a}_i \notin A_i^\infty$ is not profitable, either. ■

Note that Proposition 3 only improves on Theorem 1 at low discount factors: for high discount factors, $A = S (A) = A^\infty$, so (14) reduces to $\hat{W}^* \neq \emptyset$. However, as $\hat{W}^*$ can be empty only for low discount factors, this is precisely the case where an improvement is needed.\(^{18}\)

In order to be able to use Proposition 3 to give a recursive upper bound on $E (\delta, p)$ when $\hat{W}^* \neq \emptyset$, we must characterize $E_{\text{med}} (\delta)$ under (14). Our earlier characterization generalizes

\(^{18}\)To be clear, it is possible for $W^*$ to be empty while $A^\infty = A$. Theorem 1 and Proposition 3 only give sufficient conditions: we are not claiming that they cover every possible case.
easily. In particular, the following definitions are analogous to Definitions 2 and 3.

**Definition 4** For any set \( V \subseteq \mathbb{R}^{|I|} \), a correlated action profile \( \alpha \in \Delta (\text{supp}(\delta)) \) is \( \text{supp}(\delta) \)-enforceable on \( V \) by a mapping \( \gamma : \text{supp}(\delta) \rightarrow V \) such that, for each player \( i \), and action \( a_i \in \text{supp} \alpha_i \),

\[
\mathbb{E}^\alpha [(1 - \delta) u_i (a_i, a_{-i}) + \delta \gamma (a_i, a_{-i})] \geq \max_{a_i' \in A_i} \mathbb{E}^\alpha [(1 - \delta) u_i (a_i', a_{-i})] + \delta \min_{a_{-i} \in \Delta(\text{supp}(\delta))} \max_{a_i \in A_i} u_i (\hat{a}_i, \alpha_{-i}) .
\]

**Definition 5** A payoff vector \( v \in \mathbb{R}^{|I|} \) is \( \text{supp}(\delta) \)-decomposable on \( V \) if there exists a correlated action profile \( \alpha \in \Delta (\text{supp}(\delta)) \) which is \( \text{supp}(\delta) \)-enforced on \( V \) by some mapping \( \gamma \) such that

\[ v = \mathbb{E}^\alpha [(1 - \delta) u (a) + \delta \gamma (a)]. \]

Let \( \tilde{B}^{\text{supp}(\delta)} (V) = \{ v \in \mathbb{R}^{|I|} : v \text{ is } \text{supp}(\delta) \text{-decomposable on } V \} \).

Let \( W^{\text{supp}(\delta), 1} = u (\text{supp}(\delta)) \), let \( W^{\text{supp}(\delta), n} = \tilde{B}^{\text{supp}(\delta)} (W^{\text{supp}(\delta), n-1}) \) for \( n > 1 \), and let \( W^{\text{supp}(\delta), \infty} = \lim_{n \rightarrow \infty} W^{\text{supp}(\delta), n} \). We have the following.

**Proposition 4** If \( \text{int} \big( \bigcap_{i \in I} \tilde{W}_i \cap u(\mathcal{A}^\infty) \big) \neq \emptyset \), then \( \overline{E_{\text{med}}(\delta)} = W^{\mathcal{A}^\infty, \infty} \).

**Proof.** Given that \( \text{supp}(\delta) = \mathcal{A}^\infty \) by Proposition 3, the proof is analogous to the proof of Theorem 2. □

As an example of how Propositions 3 and 4 can be applied, one can check that applying the operator \( S \) in the Bertrand example in Section 7 for any \( \delta \in (\frac{1}{4}, \frac{5}{8}) \) yields \( \mathcal{A}^\infty = \{ W, L, M \} \times \{ W, L, M \} \)—ruling out the efficient action profile \( \{ H, H \} \)—and \( \text{int} \big( \bigcap_{i \in I} \tilde{W}_i \cap u(\mathcal{A}^\infty) \big) \neq \emptyset \). We can then compute \( \overline{E_{\text{med}}(\delta)} \) by applying the operator \( \tilde{B}^{\mathcal{A}^\infty} \).

**9.3 What if There are More Than Two Players?**

The condition that \( \tilde{W}^* \neq \emptyset \) no longer guarantees that mediated perfect monitoring outperforms private monitoring when there are more than two players. We record this as a proposition.

**Proposition 5** There are games with \( |I| > 2 \) where \( \tilde{W}^* \neq \emptyset \) but \( \sup_{v \in E(\delta)} \lambda \cdot v > \max_{v \in \overline{E_{\text{med}}(\delta)}} \lambda \cdot v \) for some non-negative Pareto weight \( \lambda \in \Lambda_+. \)
Proof. Consider the following example. There are five players and $A_i = \{a_i, b_i\}$ for $i \in \{1, 2, 3, 4\}$. Player 5 is a dummy player who takes no action and receives payoff 1 if the action profile is $(a_1, b_2, a_3, a_4)$ or $(b_1, a_2, a_3, a_4)$, and receives payoff 0 otherwise. The other players’ payoffs are as follows:

<table>
<thead>
<tr>
<th></th>
<th>$a_1$</th>
<th>$b_2$</th>
<th>$a_1$</th>
<th>$b_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$a_2$</td>
<td>0, 0, 0, 0</td>
<td>0, 1, -1, 1</td>
<td>$a_2$</td>
<td>0, 0, 0, 0</td>
</tr>
<tr>
<td>$b_1$</td>
<td>1, 0, 1, -1</td>
<td>1, 1, 0, 0</td>
<td>$b_1$</td>
<td>0, 0, 0, 1</td>
</tr>
<tr>
<td>$(a_3, a_4)$</td>
<td>(a_3, a_4)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$a_2$</td>
<td>0, 0, 0, 0</td>
<td>0, 0, 1, 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$b_1$</td>
<td>0, 0, -1, 0</td>
<td>0, 0, 0, 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$(b_3, a_4)$</td>
<td>(b_3, a_4)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$a_1$</td>
<td>10, 10, 10, 10</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$b_1$</td>
<td>10, 10, 10, 10</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note that players 1 and 3 have an incentive to deviate at profile $(a_1, b_2, a_3, a_4)$ and players 2 and 4 have an incentive to deviate at profile $(b_1, a_2, a_3, a_4)$.

Let $\delta = \frac{\sqrt{5} - 1}{2}$. Note that $u_i = 0$ for all $i$; $d_1 = d_2 = 1$, $d_3 = d_4 = 10$, and $d_5 = 0$; and hence $w_1 = w_2 = \frac{\sqrt{5} - 1}{2}$, $w_3 = w_4 = \frac{\sqrt{5} - 1}{2}$ (10), and $w_5 = 0$. Therefore, for example, the feasible payoff vector $(9.05, 9.05, 9, 9, 0.1)$ is an element of $\tilde{W}^*$.

Let $\lambda = (0, 0, 0, 0, 1)$: that is, we maximize player 5’s payoff. We show that player 5 cannot receive payoff 1 in every period in any equilibrium with mediated perfect monitoring, while this can occur for some private monitoring structure.

We first derive the impossibility result for mediated perfect monitoring.

Claim 1: If player 5 receives payoff 1 in every period, then the on-path continuation payoff for each player $i \in \{1, 2\}$ starting from any period is at most $\delta$.

Proof: If player 5 receives payoff 1 in every period, all on-path actions are either $(a_1, b_2, a_3, a_4)$ or $(b_1, a_2, a_3, a_4)$. Omitting player 3 and 4’s actions and payoffs, let $(w_1^a, w_2^a)$ denote continuation payoffs following $(a_1, b_2)$, and let $(w_1^b, w_2^b)$ denote continuation payoffs following $(b_1, a_2)$. Then player 1’s incentive compatibility constraint is $u_1^a \geq \frac{1-\delta}{\delta}$, and player 2’s incentive compatibility constraint is $w_2^b \geq \frac{1-\delta}{\delta}$. Note also that $w_1^a + w_2^a = w_1^b + w_2^b = 1$ and $w_1^a, w_2^a, w_1^b, w_2^b \geq 0$. 

35
Letting $p$ denote the probability of $(b_1, a_2, a_3, a_4)$, suppose we try to maximize player 1’s payoff (the argument for player 2 is symmetric):

$$\max_{p, w_1^a, w_1^b} \ (1 - \delta) p + \delta \left( (1 - p) w_1^a + pw_1^b \right)$$

subject to $w_1^a \geq \frac{1 - \delta}{\delta}$ and $1 - w_1^b \geq \frac{1 - \delta}{\delta}$. At a solution, $w_1^a = 1$ and $w_1^b = \frac{2\delta - 1}{\delta}$. Hence, the objective equals

$$(1 - \delta) p + \delta (1 - p) + \delta p \frac{2\delta - 1}{\delta} = \delta.$$ 

Claim 2: If player 5 receives payoff 1 in every period, then after $(a_1, b_2, a_3, a_4)$ is played in period $t$, $(b_1, a_2, a_3, a_4)$ is played with probability greater than $\frac{1}{2}$ in period $t + 1$; and after $(b_1, a_2, a_3, a_4)$ is played in period $t$, $(a_1, b_2, a_3, a_4)$ is played with probability greater than $\frac{1}{2}$ in period $t + 1$.

Proof: By Claim 1, the best continuation payoff for player 1 from period $t + 2$ is $\delta$. Hence, for player 1 to play $a_1$ in period $t$, the probability $p$ of $(b_1, a_2, a_3, a_4)$ in period $t + 1$ (conditional on $(a_1, b_2, a_3, a_4)$ in period $t$), must satisfy

$$(1 - \delta) \leq \delta (1 - \delta) p + \delta^2 \times \delta,$$

or $p \geq \frac{1 - \delta - \delta^3}{\delta (1 - \delta)}$. Noting that $\delta = \frac{\sqrt{5} - 1}{2}$ satisfies $1 - \delta = \delta^2$, this is equivalent to $p \geq \frac{\sqrt{5} - 1}{2}$.

Claim 3: If player 5 receives payoff 1 in every period, then the continuation payoff for each player $i \in \{3, 4\}$ starting from any period equals 0.

Proof: As all on-path actions are either $(b_1, a_2, a_3, a_4)$ or $(a_1, b_2, a_3, a_4)$, player 3 and 4’s continuation payoffs from any period sum to 0, and each must weakly exceed the minmax payoff of 0. Hence, both continuation payoffs must equal 0.

Claim 4: There is no equilibrium in which player 5 receives payoff 1 in every period.

Proof: Suppose such an equilibrium exists. Then all on-path actions are either $(a_1, b_2, a_3, a_4)$ or $(b_1, a_2, a_3, a_4)$. Suppose $(a_1, b_2, a_3, a_4)$ is played in period 1. Then, by Claim 2, $(b_1, a_2, a_3, a_4)$ is played in period 2 with probability greater than $\frac{1}{2}$. Hence, player 4 receives a negative instantaneous payoff in period 2, and by Claim 3 her continuation payoff from period 3 is non-positive, which leaves her with a negative total continuation payoff from period 2, a contradiction. If instead $(a_1, b_2, a_3, a_4)$ is played in period 1, then player 3 is left with a
negative continuation payoff from period 2.

Turning to private monitoring, suppose that under the universal monitoring structure the mediator randomizes with equal probability between the following two sequences:

\[(a_1, b_2, a_3, a_4) \rightarrow (b_1, a_2, a_3, a_4) \rightarrow (a_1, b_2, a_3, a_4) \rightarrow (b_1, a_2, a_3, a_4) \rightarrow \cdots\]

\[(b_1, a_2, a_3, a_4) \rightarrow (a_1, b_2, a_3, a_4) \rightarrow (b_1, a_2, a_3, a_4) \rightarrow (a_1, b_2, a_3, a_4) \rightarrow \cdots\]

Players 3 and 4 then always believe that players 1 and 2 play \((a_1, b_2)\) and \((b_1, a_1)\) with equal probability, so they are playing static best responses. Finally, with \(\delta = \sqrt{\frac{5}{2}} - 1\), the deviation gain of 1 for player \(i \in \{1, 2\}\) is equal to the continuation payoff of \(\delta + \delta^3 + \cdots = \frac{\delta}{1 - \delta^2}\).

We note that, in the proof of Proposition 5, the universal information structure can be replaced by a stationary private monitoring structure with ex ante correlation as follows: (1) let each player have an additional action \(c_i\), with the property that all players receive payoff 0 if anyone plays \(c_i\); (2) specify that all players observe signal \(z\) if the action profile equals \((a_1, b_2, a_3, a_4)\) or \((b_1, a_2, a_3, a_4)\) and observe signal \(z'\) otherwise; (3) construct a correlated equilibrium by having only players 1 and 2 observe the outcome of a randomizing device at the beginning of the game, and having the players play as in the proof of Proposition 5 so long as signal \(z\) realizes, switching to action profile \((c_1, c_2, c_3, c_4)\) if signal \(z'\) realizes.

To see where the proof of Theorem 1 breaks down when \(|I| > 2\), recall that the proof is based on the fact that, for any Pareto-efficient payoff \(v\), if \(v \notin W_i\) for one player \(i\) then it must be the case that \(v \in W_j\) for the other player \(j\). This implies that incentive compatibility is a problem only for one player at a time, which lets us construct an equilibrium with perfect monitoring by basing continuation play only on that player’s past recommendations (which she necessarily knows in any private monitoring structure). On the other hand, if there are more than two players, several players’ incentive compatibility constraints might bind at once when we publicize past recommendations. The proof of Theorem 1 then cannot get off the ground.

We can however say some things about what happens with more than two players.

First, the argument in the proof of Proposition 3 that \(\text{supp}(\delta) = A^\infty\) whenever \(\text{int}(\bigcap_{i \in I} \bar{W}_i \cap \text{cou}(A^\infty))\) \(\emptyset\) does not rely on \(|I| = 2\). Thus, when \(\text{int}(\bigcap_{i \in I} \bar{W}_i \cap \text{cou}(A^\infty)) \neq \emptyset\), we can characterize the set of supportable actions for any number of players. This is sometimes already enough.
to imply a non-trivial upper bound on payoffs.

Second, Lemma 1 implies that if a payoff vector $v \in \tilde{F}$ satisfies $v_i > u_i + \frac{1-\delta}{\delta}d_i$ for all $i \in I$, then $v \in E_{\text{med}}(\delta)$. This shows that private monitoring cannot do “much” better than mediated perfect monitoring when the players are at least moderately patient (e.g., it cannot do more than order $1 - \delta$ better). It also shows that the usual full-dimensionality conditions for the perfect monitoring folk theorem (Fudenberg and Maskin, 1986; Abreu, Dutta, and Smith, 1994) are not needed under mediated perfect monitoring.

Third, suppose there is a player $i$ whose opponents $-i$ all have identical payoff functions: $\exists i : \forall j, j' \in I \setminus \{i\}$, $u_j(a) = u_{j'}(a)$ for all $a \in A$. Then the proof of Theorem 1 can be adapted to show that private monitoring cannot outperform mediated perfect monitoring in a direction where the extremal payoff vector $v$ lies in $\bigcap_{j \in -i} W_j$ (but not necessarily in $W_i$). For example, if the game involves one firm and many identical consumers, then the consumers’ best equilibrium payoff under mediated perfect monitoring is at least as good as under private monitoring. We can also show that the same result holds if the preferences of players $-i$ are sufficiently close to each other.

Finally, in a companion paper (Sugaya and Wolitzky, 2016) we investigate repeated $n$-player oligopoly games and show that private monitoring cannot outperform mediated perfect monitoring for any number of players and any discount factor in a class of “concave” games which includes linear Cournot and differentiated-product Bertrand competition.

## 10 Conclusion

This paper gives a simple sufficient condition ($\delta > \delta^*$) under which the equilibrium payoff set in a two-player repeated game with mediated perfect monitoring is a tight, recursive upper bound on the equilibrium payoff set in the same game with any imperfect private monitoring structure. There are at least three perspectives from which this result may be of interest. First, it shows that simple, recursive methods can be used to upper-bound the equilibrium payoff set in a repeated game with imperfect private monitoring at a fixed discount factor, even though the problem of recursively characterizing this set seems intractable. Second, it characterizes the set of payoffs that can arise in a repeated game for some monitoring structure. Third, it shows that information is valuable in mediated repeated games, in that
players cannot benefit from imperfections in the monitoring technology when $\delta > \delta^*$. These different perspectives on our results suggest different questions for future research. Do moderately patient players always benefit from any improvement in the monitoring technology, or only from going all the way to perfect monitoring? Is it possible to characterize the set of payoffs that can arise for some monitoring structure even if $\delta < \delta^*$? If we do know the monitoring structure under which the game is being played, is there a general way of using this information to tighten our upper bound? Answering these questions may improve our understanding of repeated games with private monitoring at fixed discount factors, even if a full characterization of the equilibrium payoff set in such games remains out of reach.

Appendix A: Proof of Proposition 1

Mediated Perfect Monitoring

As the players’ stage game payoffs from any profile other than $(U, L)$ sum to at most 3, it follows that the players’ per-period payoffs may sum to more than 3 only if $(U, L)$ is played in some period $t$ with positive probability. For this to occur in equilibrium, player 1’s expected continuation payoff from playing $U$ must exceed her expected continuation payoff from playing $D$ by more than $(1 - \delta) 1 = \frac{5}{6}$, her instantaneous gain from playing $D$ rather than $U$. In addition, player 1 can guarantee herself a continuation payoff of 0 by always playing $D$, so her expected continuation payoff from playing $U$ must exceed $\frac{1}{\delta} \left( \frac{5}{6} \right) = 5$. This is possible only if the probability that $(T, M)$ is played in period $t + 1$ when $U$ is played in period $t$ exceeds the number $p$ such that

$$\left( 1 - \frac{1}{6} \right) \left[ p \left( \frac{5}{6} \right) + (1 - p) \left( \frac{5}{3} \right) \right] + \frac{1}{6} \left( \frac{5}{6} \right) = 5,$$

or $p = \frac{3}{5}$. In particular, there must exist a period $t + 1$ history $h_2^{t+1}$ of player 2’s such that $(T, M)$ is played with probability at least $\frac{3}{5}$ in period $t + 1$ conditional on reaching $h_2^{t+1}$. At such a history, player 2’s payoff from playing $M$ is at most

$$\left( 1 - \frac{1}{6} \right) \left[ \frac{3}{5} \left( -3 \right) + \frac{2}{5} \left( 3 \right) \right] + \frac{1}{6} \left( 3 \right) = 0.$$
On the other hand, noting that player 2 can guarantee himself a continuation payoff of 0 by playing \( \frac{1}{2}L + \frac{1}{2}M \), player 2’s payoff from playing \( L \) at this history is at least

\[
\left(1 - \frac{1}{6}\right)\left[\frac{3}{5}(3) + \frac{2}{5}(-3)\right] + \frac{1}{6}(0) = \frac{1}{2}.
\]

Therefore, player 2 has a profitable deviation, so no such equilibrium can exist.

**Private Monitoring**

Consider the following imperfect private monitoring structure. Player 2’s action is perfectly observed. Player 1’s action is perfectly observed when it equals \( T \) or \( B \). When player 1 plays \( U \) or \( D \), player 2 observes one of two possible private signals, \( m \) and \( r \). Whenever player 1 plays \( U \), player 2 observes signal \( m \) with probability \( \frac{1}{2} \); whenever player 1 plays \( D \), player 2 observes signals \( m \) and \( r \) with probability \( \frac{1}{2} \) each.

We now describe a strategy profile under which the players’ payoffs sum to \( \frac{23}{7} \approx 3.29 \).

*Player 1’s strategy:* In each odd period \( t = 2n + 1 \) with \( n = 0, 1, ..., \), player 1 plays \( \frac{1}{3}U + \frac{2}{3}D \). Let \( a_1(n) \) denote the realization of this mixture. In the even period \( t = 2n + 2 \), if the previous action \( a_1(n) \) equals \( U \), then player 1 plays \( T \); if the previous action \( a_1(n) \) equals \( D \), then player 1 plays \( B \). If in the previous period player 1 deviated to \( T \) or \( B \), then player 1 plays \( D \).

*Player 2’s strategy:* In each odd period \( t = 2n + 1 \) with \( n = 0, 1, ..., \), player 2 plays \( L \). Let \( y_2(n) \) denote the realization of player 2’s private signal. In the even period \( t = 2n + 2 \), if the previous private signal \( y_2(n) \) equals \( m \), then player 2 plays \( M \); if the previous signal \( y_2(n) \) equals \( r \), then player 2 plays \( R \). If in the previous period player 1 deviated to \( T \) or \( B \), then player 2 plays \( R \).

We check that this strategy profile, together with any consistent belief system, is a sequential equilibrium.

In an odd period, player 1’s payoff from \( U \) is the solution to \( v = \frac{5}{6}(2) + \frac{1}{6}(6) + \frac{1}{6}v \).

On the other hand, her payoff from \( D \) is \( \frac{5}{6}(3) + \frac{15}{6}(0) + \frac{1}{6}v \). Hence, player 1 is indifferent between \( U \) and \( D \) (and clearly prefers either of these to \( T \) or \( B \)).

In addition, playing \( L \) is a myopic best response for player 2, player 1’s continuation play is independent of player 2’s action, and the distribution of player 2’s signal is also
independent of player 2’s action. Hence, playing L is optimal for player 2.

Next, in an even period, it suffices to check that both players always play myopic best responses, as in even periods continuation play is independent of realized actions and signals. If in the previous period player 1 deviated to T or B, then the players play the static Nash equilibrium (D, R). If player 1’s last action was \( a_1(n) = U \), then she believes that player 2’s signal is \( y_2(n) = m \) with probability 1 and thus that he will play M. Hence, playing T is optimal. If instead player 1’s last action was \( a_1(n) = D \), then she believes that player 2’s signal is equal to \( m \) and \( r \) with probability \( \frac{1}{2} \) each, and thus that he will play \( \frac{1}{2}M + \frac{1}{2}R \). Hence, both T and B are optimal.

On the other hand, if player 2 observes signal \( y_2(n) = m \), then his posterior belief that player 1’s last action was \( a_1(n) = U \) is

\[
\frac{\frac{1}{3}(1)}{\frac{1}{3}(1) + \frac{2}{3}(\frac{1}{2})} = \frac{1}{2}.
\]

Hence, player 2 is indifferent among all of his actions. If player 2 observes \( y_2(n) = r \), then his posterior is that \( a_1(n) = D \) with probability 1, so that M and R are optimal.

Finally, expected payoffs under this strategy profile in odd periods sum to \( \frac{1}{3}(4) + \frac{2}{3}(3) = \frac{10}{3} \), and in even periods sum to 3. Therefore, per-period expected payoffs sum to

\[
\left( 1 - \frac{1}{6} \right) \left( \frac{10}{3} + \frac{1}{6}(3) \right) \left( 1 + \frac{1}{6^2} + \frac{1}{6^4} + \ldots \right) = \frac{23}{7}.
\]

Three remarks on the proof: First, the various indifferences in the above argument result only because we have chosen payoffs to make the example as simple as possible. One can modify the example to make all incentives strict.\(^{19}\) Second, players’ payoffs are measurable with respect to their own actions and signals. In particular, the required realized payoffs for player 2 are as follows:

<table>
<thead>
<tr>
<th>(Action,Signal) Pair:</th>
<th>(L, m)</th>
<th>(L, r)</th>
<th>(M, m)</th>
<th>(M, r)</th>
<th>(R, m)</th>
<th>(R, r)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Realized Payoff:</td>
<td>2</td>
<td>-2</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

\(^{19}\)The only non-trivial step in doing so is giving player 1 a strict incentive to mix in odd periods. This can be achieved by introducing correlation between the players’ actions in odd periods.
Third, a similar argument shows that imperfect public monitoring with private strategies can also outperform mediated perfect monitoring.\footnote{Here is a sketch: Modify the current example by adding a strategy $L'$ for player 2, which is an exact duplicate of $L$ as far as payoffs are concerned, but which switches the interpretation of signals $m$ and $r$. Assume that player 1 cannot distinguish between $L$ and $L'$, and modify the equilibrium by having player 2 play $\frac{1}{2}L + \frac{1}{2}L'$ in odd periods. Then, even if the signals $m$ and $r$ are publicly observed, their interpretations will be private to player 2, and essentially the same argument as with private monitoring applies.}

**Appendix B: Proof of Lemma 6**

It is useful to introduce a family of auxiliary value functions $(w^T)_{T=1}^{\infty}$ and $(w^{*,T})_{T=1}^{\infty}$, which will converge to $w$ and $w^*$ pointwise in $r^t$ as $T \to \infty$. For periods $t \geq T$, define

$$w^T(r^t) = w^\bar{r}(r^t) \text{ and } w^{*,T}(r^{t-1}) = w^\bar{r}(r^{t-1}).$$

(16)

On the other hand, for periods $t \leq T - 1$, define $w^{*,T}(r^t)$, $\rho^T(r^t)$, and $w^T(r^{t+1})$ recursively, as follows. First, define

$$w^{*,T}(r^t) = (1 - \delta) u(\mu(r^t)) + \delta \mathbb{E} [w^T(r^{t+1}) | r^t].$$

(17)

Note that, for $t = T - 1$, this definition is compatible with (16). Second, given $w^{*,T}(r^t)$, define

$$w^T(r^t) = 1_{\{w^\bar{r}(r^t) \in W_1\}} \left\{ \rho^T(r^t) w^{*,T}(r^t) + (1 - \rho^T(r^t)) \bar{w}^1 + 1_{\{w^\bar{r}(r^t) \notin W_1\}} \bar{w}^1 \right\},$$

(18)

where, when $w^\bar{r}(r^t) \in W_1$, $\rho^T(r^t)$ is the largest number in $[0, 1]$ such that

$$\rho^T(r^t) w^{*,T}(r^t) + (1 - \rho^T(r^t)) \bar{w}^1 \geq w^\bar{r}(r^t).$$

(19)

We show that $w^{*,T}$ converges to $w^*$.

**Lemma 7** \(\lim_{T \to \infty} w^{*,T}(r^t) = w^*(r^t)\) \text{ for all } r^t \in A^t.

**Proof.** By Lemma 5, it suffices to show that $F(w^T) = w^{T+1}$. For $t \geq T + 1$, (16) implies that $w^{*,T+1}(r^{t-1}) = w^\bar{r}(r^{t-1})$. On the other hand, given $w^T$, $w^*(w^T_2)$ is the value calculated
according to (8). Since \( w^T(r^t) = w^\mu(r^t) \) by (16), we have \( w^*(w_2^T)(r^{t-1}) = w^\mu(r^{t-1}) \) by (8). Hence,

\[
w^*(w_2^T)(r^{t-1}) = w^{*T+1}(r^{t-1}). \tag{20}
\]

For \( t \leq T \), by (17), we have

\[
w^{*T+1}(r^t) = (1 - \delta) u(\bar{\mu}(r^t)) + \delta \mathbb{E}[w^{T+1}(r^{t+1})|r^t].
\]

By (18),

\[
w^{T+1}(r^t) = \mathbb{1}_{\{\bar{\mu}(r^t) \in W_1\}} \left\{ \rho^{T+1}(r^t)w^{*T+1}(r^t) + (1 - \rho^{T+1}(r^t)) \tilde{w}^1 \right\} + \mathbb{1}_{\{\bar{\mu}(r^t) \notin W_1\}} \tilde{w}^1
\]

where the second equality follows from (20) for \( t = T \), and follows by induction for \( t < T \).

Recall that \( \rho^{T+1} \) is defined by (19). On the other hand, \( \rho(w^T)(r^t) \) is defined in (10) using \( w^* = w^*(w^T) \). Since \( w^{*T+1}(r^t) = w^*(w_2^T)(r^t) \), we have \( \rho^{T+1}(r^t) = \rho(w^T)(r^t) \). Hence,

\[
w^{T+1}(r^t) = \mathbb{1}_{\{\bar{\mu}(r^t) \in W_1\}} \left\{ \rho(w^T)(r^t)w^*(w^T)(r^t) + (1 - \rho(w^T)(r^t)) \tilde{w}^1 \right\} + \mathbb{1}_{\{\bar{\mu}(r^t) \notin W_1\}} \tilde{w}^1.
\]

as desired. \( \blacksquare \)

As \( w^{*T}(r^t) \), \( w^T(r^t) \), and \( \rho^T(r^t) \) converge to \( w^*(r^t) \), \( w(r^t) \), and \( \rho(r^t) \) by Lemma 7, the following lemma implies Lemma 6:

**Lemma 8** For all \( t = 1, \ldots, T - 1 \), if \( w^\mu(r^t) \in W_1 \), then \( \rho^T(r^t)w^{*T}(r^t) + (1 - \rho^T(r^t)) \tilde{w}^1 \) Pareto dominates \( w^\mu(r^t) \).

**Proof.** For \( t = T - 1 \), the claim is immediate since \( w^{*T}(r^t) = w^\mu(r^t) \) and so \( \rho^T(r^t) = 1 \).

Suppose that the claim holds for each period \( \tau \geq t + 1 \). We show that it also hold for period \( t \). By construction, \( \rho^T(r^t)w^{*T}(r^t) + (1 - \rho^T(r^t)) \tilde{w}^1 \geq w^\mu_2(r^t) \). Thus, it suffices to show that \( \rho^T(r^t)w^*_1(r^t) + (1 - \rho^T(r^t)) \tilde{w}^1 \geq w^\mu_1(r^t) \).
Note that

\[ w^{*T}(r^t) \]
\[ = (1 - \delta) u (\tilde{\mu}(r^t)) + \delta \mathbb{E} [w^T(r^{t+1}) | r^t] \]
\[ = (1 - \delta) u (\tilde{\mu}(r^t)) + \delta \left\{ \sum_{r^{t+1} : w^\beta (r^{t+1}) \in W_1} \Pr^\beta (r^{t+1} | r^t) \left\{ \rho^T(r^{t+1}) w^{*T}(r^{t+1}) + (1 - \rho^T(r^{t+1})) \bar{w}^1 \right\} + \sum_{r^{t+1} : w^\beta (r^{t+1}) \notin W_1} \Pr^\beta (r^{t+1} | r^t) \bar{w}^1 \right\} , \]

while

\[ w^\beta (r^t) = (1 - \delta) u (\tilde{\mu}(r^t)) + \delta \sum_{r^{t+1}} \Pr^\beta (r^{t+1} | r^t) w^\beta (r^t). \]

Hence,

\[ w^{*T}(r^t) - w^\beta (r^t) \]
\[ = \delta \left\{ \sum_{r^{t+1} : w^\beta (r^{t+1}) \in W_1} \Pr^\beta (r^{t+1} | r^t) \left\{ \rho^T(r^{t+1}) w^{*T}(r^{t+1}) + (1 - \rho^T(r^{t+1})) \bar{w}^1 - w^\beta (r^{t+1}) \right\} + \sum_{r^{t+1} : w^\beta (r^{t+1}) \notin W_1} \Pr^\beta (r^{t+1} | r^t) \bar{w}^1 - w^\beta (r^{t+1}) \right\} . \]

When \( w^\beta (r^{t+1}) \in W_1 \), the inductive hypothesis implies that

\[ \rho^T(r^{t+1}) w^{*T}(r^{t+1}) + (1 - \rho^T(r^{t+1})) \bar{w}^1 - w^\beta (r^{t+1}) \geq 0. \]

On the other hand, note that

\[ \sum_{r^{t+1} : w^\beta (r^{t+1}) \notin W_1} \Pr^\beta (r^{t+1} | r^t) \left\{ \bar{w}^1 - w^\beta (r^{t+1}) \right\} = l(r^t) (\bar{w}^1 - \bar{w}(r^t)) \]

for some number \( l(r^t) \geq 0 \) and vector \( \bar{w}(r^t) \notin W_1 \). In total, we have

\[ w^{*T}(r^t) = w^\beta (r^t) + l(r^t) (\bar{w}^1 - \bar{w}(r^t)) \]  

(21)

for some number \( l(r^t) \geq 0 \) and vector \( \bar{w}(r^t) \leq \bar{w}(r^t) \notin W_1 \). Since \( \bar{w}^1_1 \geq \bar{w}_1(r^t) \), if \( \bar{w}^1_1 \geq w^\beta_1(r^t) \) then (21) implies that \( \min \left\{ w^{*T}_1(r^t), \bar{w}^1_1 \right\} \geq w^\beta_1(r^t) \), and therefore \( \rho^T(r^t) w^{*T}_1(r^t) + (1 - \rho^T(r^t)) \bar{w}^1_1 \geq w^\beta_1(r^t) \). In addition, if \( w^\beta(r^{t+1}) \in W_1 \) with probability one, then the
inductive hypothesis implies that \( w_2^{s,T}(r^t) \geq w_2^\beta (r^t) \), and therefore \( \rho^T(r^t) = 1 \) and
\[
\rho^T(r^t)w_1^{s,T}(r^t) + (1 - \rho^T(r^t)) \bar{w}_1^1 = w_1^{s,T}(r^t) = w_1^\beta (r^t) + l(r^t)(\bar{w}_1^1 - \bar{w}_1(r^t)) \\
\geq w_1^\beta (r^t).
\]

Hence, it remains only to consider the case where \( \bar{w}_1^1 < w_1^\beta (r^t) \) and \( l(r^t) > 0 \).

In this case, take a normal vector \( \lambda^1 \) of the supporting hyperplane of \( F \) at \( \bar{w}_1^1 \). We have \( \lambda_1^1 \geq 0 \) and \( \lambda_2 > 0 \), and in addition (as \( \dot{w}(r^t) \leq \bar{w}(r^t) \in F \) and \( w^\beta (r^t) \in F \))
\[
\lambda^1 \cdot (\bar{w}_1^1 - \dot{w}(r^t)) \geq 0, \\
\lambda^1 \cdot (\bar{w}_1^1 - w^\beta (r^t)) \geq 0.
\]

As \( \bar{w}_1^1 - \dot{w}_1(r^t) > 0 \) and \( \bar{w}_1^1 - w_1^\beta (r^t) < 0 \), we have
\[
\frac{\dot{w}_2(r^t) - \bar{w}_1^1}{\bar{w}_1^1 - \dot{w}_1(r^t)} \leq \frac{\lambda_1^1}{\lambda_2^1} \leq \frac{\bar{w}_2^1 - w_2^\beta (r^t)}{w_2^\beta (r^t) - \bar{w}_1^1}.
\]

Next, by (21), the slope of the line from \( w^\beta (r^t) \) to \( w_1^{s,T}(r^t) \) equals the slope of the line from \( \dot{w}(r^t) \) to \( \bar{w}_1^1 \). Hence,
\[
\frac{w_2^\beta (r^t) - w_2^{s,T}(r^t)}{w_1^{s,T}(r^t) - w_2^\beta (r^t)} \leq \frac{\bar{w}_2^1 - w_2^\beta (r^t)}{w_2^\beta (r^t) - \bar{w}_1^1}.
\]

In this inequality, the denominator of the left-hand side and the numerator of the right-hand side are both positive: \( w_1^{s,T}(r^t) > w_1^\beta (r^t) \) by (21) and \( l(r^t) > 0 \), while \( \bar{w}_2^1 > w_2^\beta (r^t) \) because \( w^\beta (r^t) \in W_1 \) and \( w^\beta (r^t) \neq \bar{w}_2^1 \). Therefore, the inequality is equivalent to
\[
\frac{w_2^\beta (r^t) - w_2^{s,T}(r^t)}{\bar{w}_2^1 - w_2^\beta (r^t)} \leq \frac{w_1^{s,T}(r^t) - w_1^\beta (r^t)}{w_1^\beta (r^t) - \bar{w}_1^1}.
\]

Now, let \( q \in [0, 1] \) be the number such that
\[
qw_1^{s,T}(r^t) + (1 - q) \bar{w}_1^1 = w_1^\beta (r^t).
\]
Note that
\[ 1 - \rho^T (r^t) = \frac{w^0_2 (r^t) - w^{*,T}_2 (r^t)}{\bar{w}^1_2 - w^0_2 (r^t)}, \]
while
\[ 1 - q = \frac{w^{*,T}_1 (r^t) - w^0_1 (r^t)}{w^0_1 (r^t) - \bar{w}^1_1}. \]
Hence, \( \rho^T (r^t) > q. \) Finally, we have seen that \( \bar{w}^1_1 \leq w^0_1 (r^t) \leq w^{*,T}_1 (r^t), \) so we have
\[ \rho^T (r^t) w^{*,T}_1 (r^t) + (1 - \rho^T (r^t)) \bar{w}^1_1 \geq q w^{*,T}_1 (r^t) + (1 - q) \bar{w}^1_1 = w^0_1 (r^t). \]

\section*{References}

Online Appendix: Proof of Proposition 2

We prove that $E_{\text{talk}}(\delta, p) = E_{\text{med}}(\delta)$. In our construction, players ignore private signals $y_{i,t}$ observed in periods $t = 1, 2, \ldots$. That is, only signal $y_{i,0}$ observed in period 0 is used. Hence we can see $p$ as an ex ante correlation device. Since we consider two-player games, whenever we say players $i$ and $j$, we assume that they are different players: $i \neq j$.

The structure of the proof is as follows: take any strategy of the mediator, $\tilde{\mu}$, that satisfies inequality (3) in the text (perfect monitoring incentive compatibility); and let $\tilde{v}$ be the value when the players follow $\tilde{\mu}$. Since each $\tilde{v} \in E_{\text{med}}(\delta)$ has a corresponding $\mu$ that satisfies perfect monitoring incentive compatibility, it suffices to show that, for each $\varepsilon > 0$, there exists a sequential equilibrium whose equilibrium payoff $\nu$ satisfies $\|\nu - \tilde{v}\| < \varepsilon$ in the following environment:

1. At the beginning of the game, each player $i$ receives a message $m_i^{\text{mediator}}$ from the mediator.
2. In each period $t$, the stage game proceeds as follows:
   
   (a) Given player $i$'s history $(m_i^{\text{mediator}}, (m_r^{1st}, a_r, m_r^{2nd})_{\tau=1}^{t-1})$, each player $i$ sends the first message $m_i^{1st,t}$ simultaneously.
   
   (b) Given player $i$'s history $(m_i^{\text{mediator}}, (m_r^{1st}, a_r, m_r^{2nd})_{\tau=1}^{t-1}, m_i^{1st})$, each player $i$ takes action $a_{i,t}$ simultaneously.
   
   (c) Given player $i$'s history $(m_i^{\text{mediator}}, (m_r^{1st}, a_r, m_r^{2nd})_{\tau=1}^{t-1}, m_i^{1st}, a_t)$, each player $i$ sends the second message $m_i^{2nd,t}$ simultaneously.

We call this environment “perfect monitoring with cheap talk.” To this end, from $\tilde{\mu}$, we first create a strict full-support equilibrium $\mu^*$ with mediated perfect monitoring that yields payoffs close to $\tilde{v}$. We then move from $\mu$ to a similar equilibrium $\tilde{\mu}^*$, which will be easier to transform into an equilibrium with perfect monitoring with cheap talk. Finally, from $\mu^*$, we create an equilibrium with perfect monitoring with cheap talk with the same on-path action distribution.

Construction and Properties of $\mu$

In this subsection, we consider mediated perfect monitoring throughout. Since $\tilde{\mu}^* \neq \emptyset$, by Lemma 2 in the text, there exists a strict full support equilibrium $\mu^{\text{strict}}$ with mediated perfect monitoring. As in the proof of that lemma, consider the following strategy of the mediator: In period 1, the mediator draws one of two states, $\tilde{R}_0$ and $R_{\text{perturb}}$, with probabilities $1 - \eta$ and $\eta$, respectively. In state $\tilde{R}_0$, the mediator’s recommendation is determined as follows: If no player has deviated up to period $t$, the mediator recommends $r_t$ according to $\tilde{\mu}(h_{im}^t)$. If only player $i$ has deviated, the mediator recommends $r_{-i,t}$ to player $j$ according to $\alpha_j^*$, and recommends some best response to $\alpha_j^*$ to player $i$. Multiple deviations are treated as in the proof of Lemma 1 in the text. On the other hand, in state $R_{\text{perturb}}$, the mediator follows the equilibrium $\mu^{\text{strict}}$. Let $\mu$ denote this strategy of the mediator. From now on, we fix $\eta > 0$ arbitrarily.
With mediated perfect monitoring, since \( \mu^{\text{strict}} \) has full support, player \( i \) believes that the mediator’s state is \( R_{\text{perturb}} \) with positive probability after any history. Therefore, by perfect monitoring incentive compatibility and the fact that \( \mu^{\text{strict}} \) is a strict equilibrium, it is always strictly optimal for each player \( i \) to follow her recommendation. This means that, for each period \( t \), there exist \( \varepsilon_t > 0 \) and \( T_t < \infty \) such that, for each player \( i \) and on-path history \( h_{m+1}^t \), we have

\[
(1 - \delta) \mathbb{E}^\mu \left[ u_i(r_t) \mid h_m^t, r_{i,t} \right] + \delta \mathbb{E}^\mu \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(\mu(h_m^\tau)) \mid h_m^t, r_{i,t} \right] > \max_{a_i \in A_i} (1 - \delta) \mathbb{E} \left[ u_i(a_i, r_{-i,t}) \mid h_m^t, r_{i,t} \right] + (\delta - \delta^{T_t}) \left\{ (1 - \varepsilon_t) \max_{\tilde{a}_i} u_i(\tilde{a}_i, \alpha_j^{\varepsilon_t}) + \varepsilon_t \max_{a \in A} u_i(a) \right\} + \delta^{T_t} \max_{a \in A} u_i(a). \tag{22}
\]

That is, suppose that if player \( i \) unilaterally deviates from on-path history, then player \( j \) virtually minmaxes player \( i \) for \( T_t - 1 \) periods with probability \( 1 - \varepsilon_t \). (Recall that \( \alpha_j^{\varepsilon_t} \) is the minmax strategy and \( \alpha_j^{\varepsilon_t} \) is a full support perturbation of \( \alpha_j^* \).) Then player \( i \) has a strict incentive not to deviate from any recommendation in period \( t \) on equilibrium path. Equivalently, since \( \mu \) is an full support recommendation, player \( i \) has a strict incentive not to deviate unless she herself has deviated.

Moreover, for sufficiently small \( \varepsilon_t > 0 \), we have

\[
(1 - \delta) \mathbb{E}^\mu \left[ u_i(r_t) \mid h_m^t, r_{i,t} \right] + \delta \mathbb{E}^\mu \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(\mu(h_m^\tau)) \mid h_m^t, r_{i,t} \right] > (1 - \delta^{T_t}) \left\{ (1 - \varepsilon_t) \max_{\tilde{a}_i} u_i(\tilde{a}_i, \alpha_j^{\varepsilon_t}) + \varepsilon_t \max_{a \in A} u_i(a) \right\} + \delta^{T_t} \max_{a \in A} u_i(a). \tag{23}
\]

That is, if a deviation is punished with probability \( 1 - \varepsilon_t \) for \( T_t \) periods including the current period, then player \( i \) believes that the deviation is strictly unprofitable.\(^{21}\)

For each \( t \), we fix \( \varepsilon_t > 0 \) and \( T_t < \infty \) with (22) and (23). Without loss, we can take \( \varepsilon_t \) decreasing: \( \varepsilon_t \geq \varepsilon_{t+1} \) for each \( t \).

**Construction and Properties of \( \mu^* \)**

In this subsection, we again consider mediated perfect monitoring. We further modify \( \mu \) and create the following mediator’s strategy \( \mu^* \): At the beginning of the game, for each \( i, t, \) and \( a^t \), the mediator draws \( r_{i,t}^{\text{punish}}(a^t) \) according to \( \alpha_i^{\varepsilon_t} \). In addition, for each \( i \) and \( t \), she draws \( \omega_{i,t} \in \{ R, P \} \) such that \( \omega_{i,t} = R \) (regular) and \( P \) (punish) with probability \( 1 - p_t \) and \( p_t \), respectively, independently across \( i \) and \( t \). We will pin down \( p_t > 0 \) in Lemma 9. Moreover, given \( \omega_t = (\omega_{1,t}, \omega_{2,t}) \), the mediator chooses \( r_t(a^t) \) for each \( a^t \) as follows: If \( \omega_{1,t} = \omega_{2,t} = R \), then she draws \( r_t(a^t) \) according to \( \mu(a^t)(r) \). If \( \omega_{i,t} = R \) and \( \omega_{j,t} = P \), then she draws \( r_{i,t}(a^t) \)

\(^{21}\)If the current on-path recommendation schedule \( Pr^\mu(r_{i,t} \mid h_m^t, r_{i,t}) \) is very close to \( \alpha_j^* \), then (23) may be more restrictive than (22).
from \( \Pr^\mu(r_i \mid r^\text{punish}_{j,t}(a^t)) \) while she draws \( r_{j,t}(a^t) \) randomly from \( \sum_{a_j \in A_j} \frac{\alpha_j}{|A_j|} \). Finally, if \( \omega_{1,t} = \omega_{2,t} = P \), then she draws \( r_{i,t}(a^t) \) randomly from \( \sum_{a_i \in A_i} \frac{\alpha_i}{|A_i|} \) for each \( i \) independently. Since \( \mu \) has full support, \( \mu^* \) is well defined.

As will be seen, we will take \( p_t \) sufficiently small. In addition, recall that \( \eta > 0 \) (the perturbation of \( \bar{\mu} \) to \( \mu \)) is arbitrarily. In the next subsection and onward, we construct an equilibrium with perfect monitoring with cheap talk that has the same equilibrium action distribution as \( \mu^* \). Since \( p_t \) is small and \( \eta > 0 \) is arbitrary, constructing such an equilibrium suffices to prove Proposition 2.

At the start of the game, the mediator draws \( \omega_t, r^\text{punish}_{i,t}(a^t), \) and \( r_{i,t}(a^t) \) for each \( i, t \), and \( a^t \). Given them, the mediator sends messages to the players as follows:

1. At the start of the game, the mediator sends \( \left( \left( r^\text{punish}_{i,t}(a^t) \right)_{a^t \in A^t} \right)_{t=1}^\infty \) to player \( i \).
2. In each period \( t \), the stage game proceeds as follows:
   \[ r_{i,t} = \begin{cases} r_{i,t}(a^t) & \text{if } \bar{\omega}_{i,t}(a^t) = R, \\ r^\text{punish}_{i,t}(a^t) & \text{if } \bar{\omega}_{i,t}(a^t) = P \end{cases} \]

   be the action that player \( i \) is supposed to take if she has not yet deviated. Her strategy after her own deviation is not specified.

We say that player \( i \) has unilaterally deviated if there exist \( \tau \leq t - 1 \) and a unique \( i \) such that (i) for each \( \tau' < \tau \), we have \( a_{i,\tau'} = r_{n,\tau'} \) for each \( n \in \{1, 2\} \) (no deviation happened until period \( \tau - 1 \)) and (ii) \( a_{i,\tau} \neq r_{i,\tau} \) and \( a_{j,\tau} = r_{j,\tau} \) (player \( i \) deviates in period \( \tau \) and player \( j \) does not deviate).

Note that \( \mu^* \) is close to \( \mu \) on the equilibrium path for sufficiently small \( p_t \). Hence, on-path strict incentive compatibility for player \( i \) follows from (22). Moreover, the incentive compatibility condition analogous to (23) also holds.

**Lemma 9** There exists \( \{p_t\}_{t=1}^\infty \) with \( p_t > 0 \) for each \( t \) such that it is strictly optimal for each player \( i \) to follow her recommendation: For each player \( i \) and history

\[
h^*_i \equiv \left( \left( \left( r^\text{punish}_{i,t}(a^t) \right)_{a^t \in A^t} \right)_{t=1}^\infty, a^t, (\bar{\omega}_\tau(a^t))_{\tau=1}^{t-1}, \bar{\omega}_{i,t}(a^t), (r_{i,t})_{\tau=1}^t \right),
\]

\[22\]As will be seen below, if \( \omega_{j,t} = P \), then player \( j \) is supposed to take \( r^\text{punish}_{j,t}(a^t) \). Hence, \( r_{j,t}(a^t) \) does not affect the equilibrium action. We define \( r_{j,t}(a^t) \) so that, when the mediator sends a message only at the beginning of the game (in the game with perfect monitoring with cheap talk), she sends a “dummy recommendation” \( r_{j,t}(a^t) \) so that player \( j \) does not realize that \( \omega_{j,t} = P \) until period \( t \).
if player $i$ herself has not yet deviated, we have the following two inequalities:

1. If a deviation is punished by $\alpha_j^{\varepsilon_t}$ for the next period $T_t$ periods with probability $1 - \varepsilon_t - \sum_{\tau=t}^{t+T_t-1} p_{\tau}$, then it is strictly unprofitable:

\[
(1 - \delta) E^{\mu^*} \left[ u_i(r_i,t, a_j,t) \mid h_i^t \right] + \delta E^{\mu^*} \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(r_i,\tau, a_j,\tau) \mid h_i^t, a_i,t = r_i,t \right]
\]

\[
> \max_{a_i \in A_i} (1 - \delta) E^{\mu^*} \left[ u_i(a_i, a_j,t) \mid h_i^t \right]
\]

\[
+ (\delta - \delta^{T_t}) \left\{ (1 - \varepsilon_t - \sum_{\tau=t}^{t+T_t-1} p_{\tau}) \max_{\hat{a}_i} u_i(\hat{a}_i, \alpha_j^{\varepsilon_t}) + \left( \varepsilon_t + \sum_{\tau=t}^{t+T_t-1} p_{\tau} \right) \max_{a_i \in A} u_i(a) \right\}
\]

\[
+ \delta^{T_t} \max_{a_i \in A} u_i(a).
\]

(24)

2. If a deviation is punished by $\alpha_j^{\varepsilon_t}$ from the current period with probability $1 - \varepsilon_t - \sum_{\tau=t}^{t+T_t-1} p_{\tau}$, then it is strictly unprofitable:

\[
(1 - \delta) E^{\mu^*} \left[ u_i(r_i,t, a_j,t) \mid h_i^t \right] + \delta E^{\mu^*} \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(r_i,\tau, a_j,\tau) \mid h_i^t, a_i,t = r_i,t \right]
\]

\[
> (1 - \delta^{T_t}) \left\{ (1 - \varepsilon_t - \sum_{\tau=t}^{t+T_t-1} p_{\tau}) \max_{\hat{a}_i} u_i(\hat{a}_i, \alpha_j^{\varepsilon_t}) + \left( \varepsilon_t + \sum_{\tau=t}^{t+T_t-1} p_{\tau} \right) \max_{a_i \in A} u_i(a) \right\}
\]

\[
+ \delta^{T_t} \max_{a_i \in A} u_i(a).
\]

(25)

Moreover, $E^{\mu^*}$ does not depend on the specification of player $j$’s strategy after player $j$’s own deviation, for each history $h_i^t$ such that player $i$ has not deviated.

**Proof.** Since $\mu^*$ has full support on the equilibrium path, a player $i$ who has not yet deviated always believes that player $j$ has not deviated. Hence, $E^{\mu^*}$ is well defined without specifying player $j$’s strategy after player $j$’s own deviation.

Moreover, since $p_t$ is small and $\omega_{i,t}$ is independent of $(\omega_{\tau})_{\tau=1}^{t-1}$ and $\omega_{i,t}$, given $(\bar{\omega}_{\tau}(a^t))_{\tau=1}^{t-1}$ and $\omega_{i,t}(a^t)$ (which are equal to $(\omega_{\tau})_{\tau=1}^{t-1}$ and $\omega_{i,t}$ on-path), player $i$ believes that $\bar{\omega}_{i,t}(a^t)$ is equal to $\omega_{j,t}$ and $\omega_{j,t}$ is equal to $R$ with a high probability, unless player $i$ has deviated. Since

\[
Pr^{\mu^*}(r_{j,t} \mid \bar{\omega}_{i,t}(a^t), \{\bar{\omega}_{j,t}(a^t) = R^1, h_i^t\}) = Pr^{\mu^*}(r_{j,t} \mid a^t, r_{i,t}),
\]

we have that the difference

\[
E^{\mu^*} \left[ u_i(r_i,t, a_j,t) \mid h_i^t \right] - E^{\mu} \left[ u_i(r_i,t, a_j,t) \mid r_i^t, a^t, r_{i,t} \right]
\]

is small for small $p_t$.

Further, if $p_t$ is small for each $\tau \geq t + 1$, then since $\omega_{\tau}$ is independent of $\omega_{\tau}$ with $t \leq \tau - 1$, regardless of $(\bar{\omega}_{\tau}(a^t))_{\tau=1}^{t-1}$, player $i$ believes that $\bar{\omega}_{i,\tau}(a^t) = \bar{\omega}_{j,\tau}(a^t) = R$ with high probability for $\tau \geq t + 1$ on the equilibrium path. Since the distribution of the recommendation given
$\mu^*$ is the same as that of $\mu$ given $a^t$ and $\omega_{i,t}(a^t) = \omega_{j,t}(a^t) = R$, we have that

$$
\mathbb{E}^{\mu^*} \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(r_{i,\tau}, a_{j,\tau}) \mid h_{i,t}, a_{i,t} = r_{i,t} \right] - \mathbb{E}^{\mu} \left[ (1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_i(r_{i,\tau}, a_{j,\tau}) \mid r_{i,t}, a^t, r_{i,t} \right]
$$

is small for small $p_\tau$ with $\tau \geq t + 1$.

Hence, (22) and (23) imply that, there exists $\bar{p}_t > 0$ such that, if $p_\tau \leq \bar{p}_t$ for each $\tau \geq t$, then the claims of the lemma hold. Hence, if we take $p_t \leq \min_{\tau \leq t} \bar{p}_\tau$, then the claims hold.

We fix $\{p_t\}^\infty_{t=1}$ so that Lemma 9 holds. This fully pins down $\mu^*$ with mediated perfect monitoring.

**Construction with Perfect Monitoring with Cheap Talk**

Given $\mu^*$ with mediated perfect monitoring, we define the equilibrium strategy with perfect monitoring with cheap talk such that the equilibrium action distribution is the same as $\mu^*$. We must pin down the following four objects: at the beginning of the game, what message $m^1_{i,\text{mediator}}$ player $i$ receives from the mediator; what message $m^1_{i,t}$ player $i$ sends at the beginning of period $t$; what action $a_{i,t}$ player $i$ takes in period $t$; and what message $m^2_{i,t}$ player $i$ sends at the end of period $t$.

**Intuitive Argument**

As in $\mu^*$, at the beginning of the game, for each $i$, $t$, and $a^t$, the mediator draws $r_{i,t}^{\text{punish}}(a^t)$ according to $a_{i,t}^e$. In addition, with $p_t > 0$ pinned down in Lemma 9, she draws $\omega_t \in \{R, P\}^2$ and $r_t(a^t)$ as in $\mu^*$ for each $t$ and $a^t$. She then defines $\omega_t(a^t)$ from $a^t$, $r_t(a^t)$, and $\omega_t$ as in $\mu^*$.

Intuitively, the mediator sends all the information about

$$
\left( \left( \omega_t(a^t), r_t(a^t), r_{1,t}^{\text{punish}}(a^t), r_{2,t}^{\text{punish}}(a^t) \right)_{a^t \in A^t} \right)^\infty_{t=1}
$$

through the initial messages $(m^1_{\text{mediator}}, m^2_{\text{mediator}})$. In particular, the mediator directly sends $\left( (r_{i,t}^{\text{punish}}(a^t))_{a^t \in A^t} \right)^\infty_{t=1}$ to player $i$ as a part of $m^1_{i,\text{mediator}}$. Hence, we focus on how we replicate the role of the mediator in $\mu^*$ of sending $(\omega_t(a^t), r_t(a^t))$ in each period, depending on realized history $a^t$.

The key features to establish are (i) player $i$ does not know the instructions for the other player, (ii) before player $i$ reaches period $t$, player $i$ does not know her own recommendations for periods $\tau \geq t$ (otherwise, player $i$ would obtain more information than the original equilibrium $\mu^*$ and thus might want to deviate), and (iii) no player wants to deviate (in particular, if player $i$ deviates in actions or cheap talk, then the strategy of player $j$ is as if the state were $\omega_{j,t} = P$ in $\mu^*$, for a sufficiently long time with a sufficiently high probability).

The properties (i) and (ii) are achieved by the same mechanism as in Theorem 9 of Heller, Solan and Tomala (2012, henceforth HST). In particular, without loss, let $A_i = \{1, \ldots, n_i\}$ be player $i$’s action set. We can view $r_{i,t}(a^t)$ as an element of $\{1, \ldots, n_i\}$. The mediator at the beginning of the game draws $r_i(a^t)$ for each $a^t$. 

53
Instead of sending $r_{i,t}(a^t)$ directly to player $i$, the mediator encodes $r_{i,t}(a^t)$ as follows: For a sufficiently large $N^t \in \mathbb{Z}$ to be determined, we define $p^t = N^t n_i n_j$. This $p^t$ corresponds to $p_h$ in HST. Let $Z_{p^t} \equiv \{1, ..., p^t\}$. The mediator draws $x_{i,t}^j(a^t)$ uniformly and independently from $Z_{p^t}$ for each $i$, $t$, and $a^t$. Given them, she defines

$$y_{i,t}^j(a^t) \equiv x_{i,t}^j(a^t) + r_{i,t}(a^t) \pmod{n_i}. \tag{26}$$

Intuitively, $y_{i,t}^j(a^t)$ is the “encoded instruction” of $r_{i,t}(a^t)$, and to obtain $r_{i,t}(a^t)$ from $y_{i,t}^j(a^t)$, player $i$ needs to know $x_{i,t}^j(a^t)$. The mediator gives $\left((y_{i,t}^j(a^t))_{a^t \in A^t-1}\right)_t$ to player $i$ as a part of $m_i^\text{mediator}$. At the same time, she gives $\left((x_{i,t}^j(a^t))_{a^t \in A^t-1}\right)_t$ to player $j$ as a part of $m_j^\text{mediator}$.

At the beginning of period $t$, player $j$ sends $x_{i,t}^j(a^t)$ by cheap talk as a part of $m_{j,1}^\text{t}$, based on the realized action $a^t$, so that player $i$ does not know $r_{i,t}(a^t)$ until period $t$. (Throughout the proof, the superscript of a variable represents who is informed about the variable, and the subscript represents whose recommendation the variable is about.)

In order to incentivize player $j$ to tell the truth, the equilibrium should embed a mechanism that punishes player $i$ if she tells a lie. In HST, this is done as follows: The mediator draws $\alpha_{i,t}^j(a^t)$ and $\beta_{i,t}^j(a^t)$ uniformly and independently from $Z_{p^t}$, and defines

$$u_{i,t}^j(a^t) \equiv \alpha_{i,t}^j(a^t) \times x_{i,t}^j(a^t) + \beta_{i,t}^j(a^t) \pmod{p^t}. \tag{27}$$

The mediator gives $x_{i,t}^j(a^t)$ and $u_{i,t}^j(a^t)$ to player $j$ while she gives $\alpha_{i,t}^j(a^t)$ and $\beta_{i,t}^j(a^t)$ to player $i$. In period $t$, player $j$ is supposed to send $x_{i,t}^j(a^t)$ and $u_{i,t}^j(a^t)$ to player $i$. If player $i$ receives $x_{i,t}^j(a^t)$ and $u_{i,t}^j(a^t)$ with

$$u_{i,t}^j(a^t) \neq \alpha_{i,t}^j(a^t) \times x_{i,t}^j(a^t) + \beta_{i,t}^j(a^t) \pmod{p^t}, \tag{28}$$

then player $i$ interprets that player $j$ has deviated. For sufficiently large $N^t$, since player $j$ does not know $\alpha_{i,t}^j(a^t)$ and $\beta_{i,t}^j(a^t)$, if player $j$ tells a lie about $x_{i,t}^j(a^t)$, then with a high probability, player $j$ creates a situation where (28) holds.

Since HST considers Nash equilibrium, they let player $i$ minimax player $j$ forever after (28) holds. On the other hand, since we consider sequential equilibrium, as in the proof of Lemma 2 in the text, we will create a coordination mechanism such that, if player $j$ tells a lie, then with high probability player $i$ minimaxes player $j$ for a long time and player $i$ assigns probability zero to the event that player $i$ punishes player $j$.

To this end, we consider the following coordination: First, if and only if $\bar{\omega}_{i,t}(a^t) = R$, the mediator defines $u_{i,t}^j(a^t)$ as (27). Otherwise, $u_{i,t}^j(a^t)$ is randomly drawn. That is,

$$u_{i,t}^j(a^t) \equiv \begin{cases} \alpha_{i,t}^j(a^t) \times x_{i,t}^j(a^t) + \beta_{i,t}^j(a^t) \pmod{p^t} & \text{if } \bar{\omega}_{i,t}(a^t) = R, \\ \text{uniformly distributed over } Z_{p^t} & \text{if } \bar{\omega}_{i,t}(a^t) = P. \end{cases} \tag{29}$$

Since both $\bar{\omega}_{i,t}(a^t) = R$ and $\bar{\omega}_{i,t}(a^t) = P$ happen with a positive probability, player $i$ after receiving $u_{i,t}^j(a^t)$ with $u_{i,t}^j(a^t) \neq \alpha_{i,t}^j(a^t) \times x_{i,t}^j(a^t) + \beta_{i,t}^j(a^t) \pmod{p^t}$ interprets that $\bar{\omega}_{i,t}(a^t) = P$. For notational convenience, let $\hat{\omega}_{i,t}(a^t) \in \{R, P\}$ be player $i$’s interpretation of $\bar{\omega}_{i,t}(a^t)$. After $\hat{\omega}_{i,t}(a^t) = P$, she takes period-$t$ action according to $r_{i,t}^{\text{punish}}(a^t)$. Given this inference, if player $j$ tells a lie about $u_{i,t}^j(a^t)$ with $\bar{\omega}_{i,t}(a^t) = R$, then with a high probability, she induces
a situation with $u_{i,t}(a') \neq \alpha_{i,t}(a') \times x_{i,t}(a') + \beta_{i,t}(a') \pmod{p^t}$, and player $i$ punishes player $j$ in period $t$ (without noticing player $j$’s deviation).

Second, switching to $r_{i,t}^{\text{punish}}(a')$ for period $t$ only may not suffice, if player $j$ believes that player $i$’s action distribution given $\omega_{i,t}(a') = R$ is close to the minimax strategy. Hence, we ensure that, once player $j$ deviates, player $i$ takes $r_{i,t}^{\text{punish}}(a^*)$ for a sufficiently long time.

To this end, we change the mechanism so that player $j$ does not always know $u_{i,t}(a')$. Instead, the mediator draws $p^t$ independent random variables $u_{i,t}(n, a')$ with $n = 1, ..., p^t$ uniformly from $\mathbb{Z}_{p^t}$. In addition, she draws $n_{i,t}^j(a')$ uniformly from $\mathbb{Z}_{p^t}$.

The mediator defines $u_{i,t}(n, a')$ for each $n = 1, ..., p^t$ as follows:

$$u_{i,t}(n, a') = \begin{cases} u_{i,t}^j(n, a') & \text{if } n = n_{i,t}^j(a'), \\ u_{i,t}(n, a') & \text{if otherwise,} \end{cases}$$

that is, $u_{i,t}^j(n, a')$ corresponds to $u_{i,t}(a')$ with (29) only if $n = n_{i,t}^j(a')$. For other $n$, $u_{i,t}^j(n, a')$ is completely random.

The mediator sends $n_{i,t}^j(a')$ to player $i$, and sends $\{u_{i,t}(n, a')\}_{n \in \mathbb{Z}_{p^t}}$ to player $j$. In addition, the mediator sends $n_{i,t}^j(a')$ to player $j$, where

$$n_{i,t}^j(a') = \begin{cases} n_{i,t}^j(a') & \text{uniformly distributed over } \mathbb{Z}_{p^t} \\ \text{if } \omega_{i,t-1}(a^{t-1}) = P, \\ \text{if otherwise,} \end{cases}$$

is equal to $n_{i,t}^j(a')$ if and only if last-period $\omega_{i,t-1}(a^{t-1})$ is equal to $P$.

In period $t$, player $j$ is asked to send $x_{i,t}(a')$ and $u_{i,t}(n, a')$ with $n = n_{i,t}^j(a')$, that is, send $x_{i,t}(a')$ and $u_{i,t}^j(a')$. If and only if player $j$’s messages $\hat{x}_{i,t}^j(a')$ and $\hat{u}_{i,t}^j(a')$ satisfy

$$\hat{u}_{i,t}^j(a') = \alpha_{i,t}(a') \times \hat{x}_{i,t}^j(a') + \beta_{i,t}(a') \pmod{p^t},$$

player $i$ interprets $\hat{\omega}_{i,t}(a') = R$. If player $i$ has $\hat{\omega}_{i,t}(a') = R$, then player $i$ knows that player $j$ needs to know $n_{i,t+1}^j(a^{t+1})$ to send the correct $u_{i,t+1}(n, a^{t+1})$ in the next period. Hence, she sends $n_{i,t+1}^j(a^{t+1})$ to player $j$. If player $i$ has $\hat{\omega}_{i,t}(a') = P$, then she believes that player $j$ knows $n_{i,t+1}^j(a^{t+1})$ and does not send $n_{i,t+1}(a^{t+1})$.

Given this coordination, once player $j$ creates a situation with $\hat{\omega}_{i,t}(a') = R$ but $\hat{\omega}_{i,t}(a') = P$, then player $j$ cannot receive $n_{i,t+1}^j(a^{t+1})$. Without knowing $n_{i,t+1}^j(a^{t+1})$, with a large $N^{t+1}$, with a high probability, player $j$ cannot know which $u_{i,t+1}(n, a^{t+1})$ she should send. Then, again, she will create a situation with

$$\hat{u}_{i,t+1}^j(a^{t+1}) \neq \alpha_{i,t+1}^j(a^{t+1}) \times \hat{x}_{i,t}^j(a^{t+1}) + \beta_{i,t}^j(a^{t+1}) \pmod{p^{t+1}},$$

that is, $\hat{\omega}_{i,t+1}(a^{t+1}) = P$. Recursively, player $i$ has $\hat{\omega}_{i,t}(a^*) = P$ for a long time with a high probability if player $j$ tells a lie.

Finally, if player $j$ takes a deviant action in period $t$, then the mediator has drawn $\hat{\omega}_{i,t}(a^*) = P$ for each $\tau \geq t+1$ for $a^*$ corresponding to the realized history. With $\hat{\omega}_{i,t}(a^*) = P$, in order to avoid $\hat{\omega}_{i,t}(a^*) = P$, player $j$ needs to create a situation

$$\hat{u}_{i,t}^j(a^*) = \alpha_{i,t}^j(a^*) \times \hat{x}_{i,t}^j(a^*) + \beta_{i,t}^j(a^*) \pmod{p^*}$$
without knowing \( \alpha_{i,t}^j(a^t) \) and \( \beta_{i,t}^j(a^t) \) while the mediator’s message does not tell her what is \( \alpha_{i,t}^j(a^t) \times x_{i,t}^j(a^t) + \beta_{i,t}^j(a^t) \mod p^t \) by (29). Hence, for sufficiently large \( N^\tau \), player \( j \) cannot avoid \( \hat{\omega}_{i,\tau}(a^\tau) = P \) with a nonnegligible probability. Hence, player \( j \) will be minmaxed from the next period with a high probability.

The above argument in total shows that, if player \( j \) deviates, whether in communication or action, then she will be minmaxed for sufficiently long time. Lemma 9 ensures that player \( j \) does not want to tell a lie or take a deviant action.

### Formal Construction

Let us formalize the above construction: As in (29), the mediator draws \( r_t^{\text{punish}}(a^t) \) according to \( \alpha_{i,t}^j(a^t) \); then she draws \( \omega_t \in \{R, P\}^2 \) and \( r_t(a^t) \) for each \( t \) and \( a^t \); and then she defines \( \hat{\omega}_t(a^t) \) from \( a^t, r_t(a^t) \), and \( \omega_t \) as in \( \mu^* \). For each \( t \) and \( a^t \), she draws \( x_{i,t}^j(a^t) \) uniformly and independently from \( \mathbb{Z}_{n^t} \). Given them, she defines

\[
y_{i,t}^j(a^t) \equiv x_{i,t}^j(a^t) + r_{i,t}(a^t) \mod n_i,
\]

so that (26) holds.

The mediator draws \( \alpha_{i,t}^j(a^t), \beta_{i,t}^j(a^t), \tilde{u}_{i,t}^j(a^t), v_{i,t}^j(n, a^t) \) for each \( n \in \mathbb{Z}_{n^t}, n_{i,t}^j(a^t), \) and \( \tilde{n}_{i,t}^j(a^t) \) from the uniform distribution over \( \mathbb{Z}_{n^t} \) independently for each player \( i \), each period \( t \), and each \( a^t \).

As in (29), the mediator defines

\[
w_{i,t}^j(a^t) \equiv \begin{cases} 
\alpha_{i,t}^j(a^t) \times x_{i,t}^j(a^t) + \beta_{i,t}^j(a^t) \mod p^t & \text{if } \hat{\omega}_{i,t}(a^t) = R, \\
\tilde{u}_{i,t}^j(a^t) & \text{if } \hat{\omega}_{i,t}(a^t) = P.
\end{cases}
\]

In addition, the mediator defines

\[
w_{i,t}^j(n, a^t) = \begin{cases} 
w_{i,t}^j(a^t) & \text{if } n = n_{i,t}^j(a^t), \\
v_{i,t}^j(n, a^t) & \text{if otherwise}
\end{cases}
\]

and

\[
n_{i,t}^j(a^t) = \begin{cases} 
n_{i,t}^j(a^t) & \text{if } t = 1 \text{ or } \omega_{i,t-1}(a^{t-1}) = P, \\
\tilde{n}_{i,t}^j(a^t) & \text{if } t \neq 1 \text{ and } \omega_{i,t-1}(a^{t-1}) = R,
\end{cases}
\]

as explained above.

Let us now define the equilibrium:

1. At the beginning of the game, the mediator sends

\[
m_{i}^\text{mediator} = \left( \begin{array}{c} y_{i,t}^j(a^t), \alpha_{i,t}^j(a^t), \beta_{i,t}^j(a^t), r_{i,t}^{\text{punish}}(a^t) \\ n_{i,t}^j(a^t), n_{ji,t}^j(a^t), (w_{i,t}^j(n, a^t))_{n \in \mathbb{Z}_{n^t}}, x_{i,t}^j(a^t) \end{array} \right)_{a^t \in A^{t-1}}
\]

to each player \( i \).
2. In each period $t$, the stage game proceeds as follows: In equilibrium,

$$m_{j,t}^{1st} = \begin{cases} 
  u_{i,t}(n_{i,t-1}^{2nd}, a^t), x_{i,t}^j(a^t) & \text{if } t \neq 1 \text{ and } m_{j,t-1}^{2nd} \neq \{\text{babble}\}, \\
  u_{i,t}(n_{i,t}^{2nd}(a^t), a^t), x_{i,t}^j(a^t) & \text{if } t = 1 \text{ or } m_{j,t-1}^{2nd} = \{\text{babble}\}.
\end{cases} \quad (30)$$

and

$$m_{j,t}^{2nd} = \begin{cases} 
  n_{j,t+1}^{2nd}(a^{t+1}) & \text{if } \hat{\omega}_{j,t}(a^t) = R, \\
  \{\text{babble}\} & \text{if } \hat{\omega}_{j,t}(a^t) = P.
\end{cases}$$

Note that, since $m_{j,t}^{2nd}$ is sent at the end of period $t$, the players know $a^{t+1} = (a_1, \ldots, a_t)$.

(a) Given player $i$’s history $(m_i^{\text{mediator}}, (m_i^{1st}, a_r, m_i^{2nd})_r^{t-1}, m_i^{1st})$, each player $i$ sends the first message $m_{i,t}^{1st}$ simultaneously. If player $i$ herself has not yet deviated, then

$$m_{i,t}^{1st} = \begin{cases} 
  u_{i,t}^j(m_{j,t-1}^{2nd}, a^t), x_{i,t}^j(a^t) & \text{if } t \neq 1 \text{ and } m_{j,t-1}^{2nd} \neq \{\text{babble}\}, \\
  u_{i,t}(n_{i,t}^{2nd}(a^t), a^t), x_{i,t}^j(a^t) & \text{if } t = 1 \text{ or } m_{j,t-1}^{2nd} = \{\text{babble}\}.
\end{cases}$$

Let $m_{i,t}^{1st}(u)$ be the first element of $m_{i,t}^{1st}$ (that is, either $u_{i,t}^j(m_{j,t-1}^{2nd}, a^t)$ or $u_{i,t}(n_{i,t}^{2nd}(a^t), a^t)$ on equilibrium); and let $m_{i,t}^{1st}(x)$ be the second element $(x_{i,t}^j(a^t)$ on equilibrium).

As a result, the profile of the messages $m_t^{1st}$ becomes common knowledge.

If

$$m_{j,t}^{1st}(u) \neq \alpha_{i,t}^j(a^t) \times m_{j,t}^{1st}(x) + \beta_{i,t}^j(a^t) \pmod{p^t},$$

then player $i$ interprets $\hat{\omega}_{i,t}(a^t) = P$. Otherwise, $\hat{\omega}_{i,t}(a^t) = R$.

(b) Given player $i$’s history $(m_i^{\text{mediator}}, (m_i^{1st}, a_r, m_i^{2nd})_r^{t-1}, m_i^{1st})$, each player $i$ takes action $a_{i,t}$ simultaneously. If player $i$ herself has not yet deviated, then player $i$ takes $a_{i,t} = r_{i,t}$ with

$$r_{i,t} = \begin{cases} 
  y_{i,t}^j(a^t) - m_{j,t}^{1st}(x) \pmod{n_i} & \text{if } \hat{\omega}_{i,t}(a^t) = R, \\
  r_{i,t}^{\text{punish}}(a^t) & \text{if } \hat{\omega}_{i,t}(a^t) = P.
\end{cases} \quad (32)$$

Recall that $y_{i,t}^j(a^t) \equiv x_{i,t}^j(a^t) + r_{i,t}(a^t) \pmod{n_i}$ by (26). By (30), therefore, player $i$ takes $r_{i,t}^j(a^t)$ if $\hat{\omega}_{i,t}(a^t) = R$ and $r_{i,t}^{\text{punish}}(a^t)$ if $\hat{\omega}_{i,t}(a^t) = P$ on the equilibrium path, as in $\mu^*$.

(c) Given player $i$’s history $(m_i^{\text{mediator}}, (m_i^{1st}, a_r, m_i^{2nd})_r^{t-1}, m_i^{1st}, a_t)$, each player $i$ sends the second message $m_{i,t}^{2nd}$ simultaneously. If player $i$ herself has not yet deviated, then

$$m_{i,t}^{2nd} = \begin{cases} 
  n_{i,t+1}^{2nd}(a^{t+1}) & \text{if } \hat{\omega}_{i,t}(a^t) = R, \\
  \{\text{babble}\} & \text{if } \hat{\omega}_{i,t}(a^t) = P.
\end{cases}$$

As a result, the profile of the messages $m_t^{2nd}$ becomes common knowledge. Note that $\hat{\omega}_t(a^t)$ becomes common knowledge as well on equilibrium path.

**Incentive Compatibility**

The above equilibrium has full support: Since $\hat{\omega}_t(a^t)$, and $r_t(a^t)$ have full support, $(m_1^{\text{mediator}}, m_2^{\text{mediator}})$ have full support as well. Hence, we are left to verify player $i$’s incentive not to deviate from
the equilibrium strategy, given that player $i$ believes that player $j$ has not yet deviated after any history of player $i$.

Suppose that player $i$ followed the equilibrium strategy until the end of period $t-1$. First, consider player $i$’s incentive to tell the truth about $m_{1,t}^{1st}$. In equilibrium, player $i$ sends

$$m_{1,t}^{1st} = \begin{cases} 
  u_{j,t}^i(n_{j,t-1}^{2nd}, a_t), x_{j,t}(a_t) & \text{if } m_{2,t-1}^{2nd} \neq \{\text{babble}\}, \\
  u_{j,t}^i(n_{j,t}^i(a_t), a_t), x_{j,t}(a_t) & \text{if } m_{2,t-1}^{2nd} = \{\text{babble}\}.
\end{cases}$$

The random variables possessed by player $i$ are independent of those possessed by player $j$ given $(m_{1,t}^{1st}, a_t, m_{2,t}^{2nd})_{t=1}^{\infty}$, except that (i) $u_{j,t}^i(a_t) = \alpha_{i,t}^i(a_t) \times x_{j,t}^i(a_t) + \beta_{j,t}^i(a_t) \pmod{p^t}$ if $\tilde{\omega}_{i,t}(a_t) = R$, (ii) $u_{j,t}^i(a_t) = \alpha_{j,t}^i(a_t) \times x_{j,t}^i(a_t) + \beta_{j,t}^i(a_t) \pmod{p^t}$ if $\tilde{\omega}_{j,t}(a_t) = R$, (iii) $n_{i,t}^i(a_t) = n_{1,t}^i(a_t)$ if $\omega_{i,t-1}(a_{t-1}) = P$ while $n_{i,t}^i(a_t) = n_{1,t}^i(a_t)$ if $\omega_{i,t-1}(a_{t-1}) = R$, and (iv) $n_{j,t}^j(a_t) = n_{1,t}^j(a_t)$ if $\omega_{j,t-1}(a_{t-1}) = P$ while $n_{j,t}^j(a_t) = n_{1,t}^j(a_t)$ if $\omega_{j,t-1}(a_{t-1}) = R$. Since $\alpha_{i,t}^i(a_t), \beta_{i,t}^i(a_t), \tilde{u}_{j,t}^i(a_t), v_{j,t}^i(n, a_t) n_{i,t}^i(a_t)$, and $n_{j,t}^j(a_t)$ are uniform and independent, player $i$ cannot learn $\tilde{\omega}_{i,t}(a_t), r_{i,t}(a_t)$, or $r_{j,t}(a_t)$ with $\tau \geq t$. Hence, player $i$ believes at the time when she sends $m_{1,t}^{1st}$ that her equilibrium value is equal to

$$(1 - \delta)\mathbb{E}^\mu[u_t(a_t) | h_t^i] + \delta \mathbb{E}^\mu\left[(1 - \delta) \sum_{\tau=t+1}^{\infty} \delta^{\tau-t-1} u_t(a_t) | h_t^i\right],$$

where $h_t^i$ is as if player $i$ observed $r_{i,t}(a_t)$, $a_t$, $\tilde{\omega}_{j,t}(a_t)$, and $r_{i,t}(a_t)$, and believed that $r_{\tau}(a_{\tau}) = a_{\tau}$ for each $\tau = 1, \ldots, t-1$ with $\mu^\tau$ with mediated perfect monitoring.

On the other hand, for each $\varepsilon > 0$, for a sufficiently large $N^t$, if player $i$ tells a lie in at least one element $m_{1,t}^{1st}$, then with probability $1 - \varepsilon$, player $i$ creates a situation

$$m_{1,t}^{1st}(u) \neq \alpha_{j,t}^j(a_t) \times m_{1,t}^{1st}(x) + \beta_{j,t}^j(a_t) \pmod{p^t}.$$ 

Hence, (31) (with indices $i$ and $j$ reversed) implies that $\tilde{\omega}_{j,t}(a_t) = P$.

Moreover, if player $i$ creates a situation with $\tilde{\omega}_{j,t}(a_t) = P$, then player $j$ will send $m_{2,t}^{2nd} = \{\text{babble}\}$ instead of $n_{j,t+1}^j(a_{t+1})$. Unless $\tilde{\omega}_{j,t}(a_t) = P$, since $n_{j,t+1}^j(a_{t+1})$ is independent of player $i$’s variables, player $i$ believes that $n_{j,t+1}^j(a_{t+1})$ is distributed uniformly over $\mathbb{Z}_{p^t+1}$. Hence, for each $\varepsilon > 0$, for sufficiently large $N^t$, if $\tilde{\omega}_{j,t}(a_t) = R$, then player $i$ will send $m_{1,t}^{1st}$ with

$$m_{1,t}^{1st}(u) \neq \alpha_{j,t+1}^j(a_{t+1}) \times m_{1,t}^{1st}(x) + \beta_{j,t+1}^j(a_{t+1}) \pmod{p^{t+1}}$$

with probability $1 - \varepsilon$. Then, by (31) (with indices $i$ and $j$ reversed), player $j$ will have $\tilde{\omega}_{j,t+1}(a_{t+1}) = P$.

Recursively, if $\tilde{\omega}_{j,\tau}(a_\tau) = R$ for each $\tau = t, \ldots, t + T_t - 1$, then player $i$ will induce $\tilde{\omega}_{j,\tau}(a_\tau) = P$ for each $\tau = t, \ldots, t + T_t - 1$ with a high probability. Hence, for $\varepsilon_t > 0$ and $T_t$ fixed in (22) and (23), for sufficiently large $N_t$, if $N_t \geq \tilde{N}_t$ for each $\tau \geq t$, then player $i$ will be punished for the subsequent $T_t$ periods regardless of player $i$’s continuation strategy with probability no less than $1 - \varepsilon_t - \sum_{\tau=t}^{t+T_t-1} p_\tau$. ($\sum_{\tau=t}^{t+T_t-1} p_\tau$ represents the maximum probability of having $\tilde{\omega}_{i,\tau}(a_\tau) = P$ for some $\tau$ for subsequent $T_t$ periods.) (25) implies that telling a lie gives strictly lower payoff than the equilibrium payoff. Therefore, it is optimal to tell the truth about $m_{1,t}^{1st}$. (In (25), we have shown interim incentive compatibility after knowing
\( \bar{w}_{i,t}(a^t) \) and \( r_{i,t} \) while here, we consider \( h_i^t \) before \( \bar{w}_{i,t}(a^t) \) and \( r_{i,t} \). Taking the expectation with respect to \( \bar{w}_{i,t}(a^t) \) and \( r_{i,t} \), (25) ensures incentive compatibility before knowing \( \bar{w}_{i,t}(a^t) \) and \( r_{i,t} \).

Second, consider player \( i \)'s incentive to take the action \( a_{i,t} = r_{i,t} \) according to (32) if player \( i \) follows the equilibrium strategy until she sends \( m_{i,t}^{1st} \). If she follows the equilibrium strategy, then player \( i \) believes at the time when she takes an action that her equilibrium value is equal to

\[
(1 - \delta) \mathbb{E}_{\mu^*} \left[ u_i(a_t) \mid h_i^t \right] + \delta \mathbb{E}_{\mu^*} \left[ (1 - \delta) \sum_{\tau = t+1}^{\infty} \delta^{\tau-t-1} u_i(a_t) \mid h_i^t \right],
\]

where \( h_i^t \) is as if player \( i \) observed \( \left( r_{i,t}^{\text{punish}}(a^t) \right)^\infty_{a^t \in A^{t-1} = a^t} , a^t, (\bar{w}_{i,t}^{\tau}(a^\tau))_{\tau = 1}^{t-1}, \bar{w}_{i,t}(a^t) \), and \( r_{i,t} \), and believed that \( r_{\tau}(a^\tau) = a_{\tau} \) for each \( \tau = 1, \ldots, t-1 \) with \( \mu^* \) with mediated perfect monitoring. (Compared to the time when player \( i \) sends \( m_{i,t}^{1st} \), player \( i \) now knows \( \bar{w}_{i,t}(a^t) \) and \( r_{i,t} \) on equilibrium path.)

If player \( i \) deviates from \( a_{i,t} \), then \( \bar{w}_{j,\tau}(a^\tau) = P \) by definition for each \( \tau \geq t + 1 \) and \( a^\tau \) that is compatible with \( a^t \) (that is, \( a^\tau = (a_t, a_{t+1}, \ldots, a_{\tau-1}) \) for some \( a_t, \ldots, a_{\tau-1} \)). To avoid being minmaxed in period \( \tau \), player \( i \) needs to induce \( \bar{w}_{j,\tau}(a^\tau) = R \) although \( \bar{w}_{i,t}(a^t) = P \).

Given \( \bar{w}_{j,\tau}(a^\tau) = P \), since \( \alpha_{i,t}^j(a^t), \beta_{i,t}^j(a^t), \bar{u}_{i,t}^j(a^t), v_{i,t}^j(n, a^t) \) and \( n_{i,t}^j(a^t) \) are uniform and independent (conditional on the other variables), regardless of player \( i \)'s continuation strategy, by (31) (with indices \( i \) and \( j \) reversed), player \( i \) will send \( m_{i,\tau}^{1st} \) with

\[
m_{i,\tau}^{1st}(u) = \alpha_{j,\tau}(a^\tau) x m_{i,\tau}^{1st}(x) + \beta_{j,\tau}(a^\tau) (\text{mod } p^\tau)
\]

with a high probability.

Hence, for sufficiently large \( \tilde{N}^t \), if \( N^\tau \geq \tilde{N}^t \) for each \( \tau \geq t \), then player \( i \) will be punished for the next \( T_i \) periods regardless of player \( i \)'s continuation strategy with probability no less than \( 1 - \varepsilon_t \). By (24), deviating from \( r_{i,t} \) gives a strictly lower payoff than her equilibrium payoff. Therefore, it is optimal to take \( a_{i,t} = r_{i,t} \).

Finally, consider player \( i \)'s incentive to tell the truth about \( m_{i,t}^{2nd} \). Regardless of \( m_{i,t}^{2nd} \), player \( j \)'s actions do not change. Hence, we are left to show that telling a lie does not improve player \( i \)'s deviation gain by giving player \( i \) more information.

On the equilibrium path, player \( i \) knows \( \bar{w}_{i,t}(a^t) \). If player \( i \) tells the truth, then \( m_{i,t}^{2nd} = n_{i,t+1}^i(a^{t+1}) \neq \{ \text{babble} \} \) if and only if \( \bar{w}_{i,t}(a^t) = R \). Moreover, player \( j \) sends

\[
m_{j,t+1}^{1st} = \begin{cases} u_{i,t+1}^j(m_{i,t+1}^{2nd}(a^{t+1}), a_{i,t+1}^j(a^{t+1}) & \text{if } \bar{w}_{i,t}(a^t) = R, \\ u_{i,t+1}^j(n_{i,t+1}^j(a^{t+1}), a_{i,t+1}^j(a^{t+1}) & \text{if } \bar{w}_{i,t}(a^t) = P. \end{cases}
\]

Since \( n_{i,t+1}^j(a^{t+1}) = n_{i,t+1}^j(a^{t+1}) \) if \( \bar{w}_{i,t}(a^t) = P \), in total, if player \( i \) tells the truth, then player \( i \) knows \( u_{i,t+1}^j(m_{i,t+1}^{2nd}(a^{t+1}), a_{i,t+1}^j(a^{t+1}) \) and \( x_{i,t+1}^j(a^{t+1}) \). This is sufficient information to infer \( \bar{w}_{i,t+1}(a^{t+1}) \) and \( r_{i,t+1}(a^{t+1}) \) correctly.

If she tells a lie, then player \( j \)'s messages are changed to

\[
m_{j,t+1}^{1st} = \begin{cases} u_{i,t+1}^j(m_{i,t+1}^{2nd}(a^{t+1}), a_{i,t+1}^j(a^{t+1}) & \text{if } m_{i,t+1}^{2nd} \neq \{ \text{babble} \}, \\ u_{i,t+1}^j(n_{i,t+1}^j(a^{t+1}), a_{i,t+1}^j(a^{t+1}) & \text{if } m_{i,t+1}^{2nd} = \{ \text{babble} \}. \end{cases}
\]
Since $\alpha^i_{i,t+1}(a^{t+1})$, $\beta^i_{i,t+1}(a^{t+1})$, $\tilde{\omega}^j_{i,t+1}(a^{t+1})$, $\nu^j_{i,t+1}(n,a^{t+1})$, $\bar{n}^j_{i,t+1}(a^{t+1})$, and $\bar{n}^j_{i,t+1}(a^{t+1})$ are uniform and independent conditional on $\omega_{i,t+1}(a^{t+1})$ and $r_{i,t+1}(a^{t+1})$, $u^j_{i,t+1}(n,a^{t+1})$ and $x^j_{i,t+1}(a^{t+1})$ are not informative about player $j$’s recommendation from period $t + 1$ on or player $i$’s recommendation from period $t + 2$ on, given that player $i$ knows $\omega_{i,t+1}(a^{t+1})$ and $r_{i,t+1}(a^{t+1})$. Since telling the truth informs player $i$ of $\omega_{i,t+1}(a^{t+1})$ and $r_{i,t+1}(a^{t+1})$, there is no gain from telling a lie.
